

SYNTROLEUM

PETITION FOR RULEMAKING PURSUANT TO 10 C.F.R. PART 490

TO DESIGNATE SYNTROLEUM S-2 FUEL
AS AN ALTERNATIVE FUEL
UNDER SECTION 301(2) OF THE ENERGY POLICY ACT OF 1992

PRESENTED TO THE UNITED STATES DEPARTMENT OF ENERGY
OFFICE OF GENERAL COUNSEL

BY:
SYNTROLEUM

Mark Agee, President

May 31, 2000

GLOSSARY

ANPR – Advanced Notice of Proposed Rulemaking
ATR - Autothermal Reformer Reactor
bpd – Barrels Per Day
Btu – British Thermal Unit
CAA – Clean Air Act of 1990
CH₄ - Methane
CIDI – Compression Ignition Direct-Injection
CNG – Compressed Natural Gas
CO – Carbon Monoxide
CO₂ – Carbon Dioxide
DOE – Department of Energy
EGR – Exhaust Gas Re-Circulation
EIA – Energy Information Administration
EPA – Environmental Protection Agency
EPAct – Energy Policy Act of 1992
FCC – Fluidized Catalytic Cracker
FPSO – Floating Production Storage and Offloading
FT – Fischer-Tropsch
FTP – Federal Test Procedure (EPA)
g/mi – Grams Per Mile
geg – Gasoline Equivalent Gallon
GHG – Greenhouse Gas
GREET – Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation
GREET Reformulated Diesel – Reformulated Diesel at a 50-ppm Sulfur Level
GRI – Gas Research Institute
GTL – Gas to Liquids
GVW – Gross Vehicle Weight
GWP – Global Warming Potential
HFET – EPA Highway Fuel Economy Test (EPA)
LCO – FCC Light Cycle Oil
LHV – Lower Heating Value
LNG – Liquefied Natural Gas
LPG – Liquefied Petroleum Gas
mpg – Miles Per Gallon
MTBE – Methyl-Tertiary-Butyl Ether
NMHC – Non-Methane Hydrocarbons
NO_x – Oxides of Nitrogen
N₂O – Nitrous Oxide
OPEC – Oil Producing Exporting Countries
PCF – Prototype Carbon Fund (the World Bank's)
PM – Particulate Matter
ppm – Parts Per Million
PNGV – The Partnership of New Generation of Vehicles
RFD – Reformulated Diesel at a 15 ppm Sulfur Level
RFG – Reformulated Gasoline at a 30 ppm Sulfur Level

SIDI – Spark Ignition Direct-Injection

S-2 – Syntroleum S-2 Fuel (used to denote synthetic paraffin diesel with the properties of S-2)

SO_x – Sulfur Oxides

SUV – Sport Utility Vehicles

SwRI – Southwest Research Institute

Syntroleum Process – Syntroleum's Proprietary GTL Process

tcf – Trillion Cubic Feet

THC – Total Hydrocarbons

US06 – Aggressive Driving Test Protocol (EPA)

VOC – Volatile Organic Compounds

I. **SUMMARY**

This petition requests that the Secretary initiate a rulemaking, pursuant to 10 C.F.R. Part 490, to add synthetic paraffin diesel with the properties and origin of Syntroleum S-2 fuel (referred to as “Syntroleum S-2 fuel” or “S-2”) to the list of alternative fuels in the Energy Policy Act of 1992’s (“EPAct”’s) implementing regulations at 10 C.F.R. Section 490.2. *See* 10 C.F.R. § 490.2 (1999).¹

Section 301(2) of EPAct provides that the Secretary of the Department of Energy (“DOE”) may deem a fuel an alternative fuel if the Secretary determines by rule, that the fuel (1) is substantially not petroleum, (2) would yield substantial energy security benefits, and (3) would yield substantial environmental benefits. 42 U.S.C. 13211 (2) (West 1999). S-2 meets all three requirements.

First, S-2 fuel is “substantially not petroleum” because it is a synthetic fuel that is manufactured from natural gas, using Syntroleum’s proprietary gas to liquid (“GTL”) process (the “Syntroleum Process”).

Second, the use of S-2 would yield substantial energy security benefits because it would reduce the United States’ reliance on imported oil as a transportation energy source. S-2 fuel would reduce the reliance on imported oil because it can be manufactured domestically from United States reserves of pipeline quality and sub-quality natural gas. In addition, the manufacture of S-2 abroad would create a competing fuel and force Oil Producing Exporting Countries (“OPEC”) to maintain competitive prices.

Finally, S-2 would yield substantial environmental benefits. When S-2 is used in diesel engines, its emission levels of hydrocarbon (“HC”), carbon monoxide (“CO”), oxides of nitrogen (“NO_x”), and particulate matter (“PM”) are lower than the emission levels from reformulated gasoline and diesel fuels. This environmental benefit can be realized immediately because S-2 can be used in existing conventional diesel engines. Moreover, the absence of sulfur in S-2 enables vehicles operating on S-2 to use advanced sulfur-sensitive exhaust treatment technologies, including catalytic converters and particulate traps, to achieve even lower emissions. Further, when S-2 is produced from flared or vented natural gas, S-2, on a full fuel-cycle basis, reduces total greenhouse gas (“GHG”) emissions with significant energy savings.

¹ In addition, this petition requests that the Secretary deem synthetic paraffin diesel with the properties of Syntroleum S-2 fuel (referred to as “Syntroleum S-2 fuel” or “S-2”) a replacement fuel, pursuant to Section 301(14) of the Energy Policy Act of 1992 (“EPAct”), 42 U.S.C.A. § 13211(14) (West 1999). *See infra*, note 9.

II. DESCRIPTION OF SYNTROLEUM S-2 FUEL AND ITS PRODUCTION

S-2 is a paraffinic, high-cetane distillate product suitable for conventional and advanced compression ignition engines. Additionally, it has been demonstrated to be a viable fuel for fuel cell vehicles. S-2 is physically similar to petroleum-based diesel, but it has superior combustion emission characteristics. Comparisons between key physical properties of S-2 and petroleum-based diesel are more thoroughly discussed in Section V, herein.

The Syntroleum Process (simplified process flow diagram attached as Figure 1) converts natural gas into ultra clean liquid fuels, such as S-2, using a patented GTL technology based on the Fischer-Tropsch (or “FT”) process. The feedstock to this process can be anything from pipeline quality natural gas to methane rich gas containing up to 30% inert gases, including nitrogen and carbon dioxide.² Conventional chemical scrubbers remove sulfur and mercaptans in the natural gas feed prior to conversion into synthetic liquids.

The production of S-2 essentially involves two separate catalytic reactions and the separation and treatment of products produced from the second of these reactions. The first reaction takes place in an Autothermal Reformer Reactor (“ATR”), where the natural gas feed is combined with air and a small amount of steam to form synthesis gas (carbon monoxide and hydrogen). The second reaction takes place when the synthesis gas flows into a Syntroleum designed FT reactor, containing any of several proprietary catalysts. As the synthesis gas passes over the catalyst, it is converted into hydrocarbons of various molecular weights with water as a by-product. The hydrocarbons, essentially straight chain paraffins, along with water and non-reactive gases are removed from the reactor effluent in a two-step cooling and separation process. The water is treated for re-use or disposal. Energy in the form of low British thermal units (“Btu’s”) in the tail gas is recovered and used in the process.

From the hydrocarbon product stream of the FT reactor, heavy paraffins are separated from light paraffins and sent to a hydrocracker, where they are cracked under mild operating conditions (low temperature and pressure) into lighter paraffins. The hydrocracked heavy paraffin stream is then directed, along with the light paraffins, to a fractionation unit, where via conventional distillation, S-2 is separated from the other paraffinic products and sent to storage. The hydrocracked heavy and the light paraffins are hydrotreated before fractionation, which removes essentially all of the olefins and oxygenates produced by the process.

The use of ambient air, or enriched air, is a unique characteristic of the Syntroleum Process. It provides significant capital and operating cost reductions as well as safety advantages over competitive processes, which use pure oxygen to create a

² Total volume percent of inert gases should not exceed approximately 30 % and carbon dioxide should be below 12 % for efficient conversion via the Syntroleum Process. However, technologies under evaluation are capable of utilizing gas feedstock that has higher CO₂ concentrations.

synthesis gas that is largely free of nitrogen. Energy integration is also a key component of the capital efficiency of the Syntroleum Process. The Syntroleum Process uses the nitrogen to its advantage to assist in controlling the excess heat released from the catalytic reactions. In addition, the Syntroleum Process utilizes a portion of the excess energy to drive the plant processes. Any surplus plant heat energy may be converted to electricity, used to desalinate water, and/or used to increase process carbon efficiency. Fuel plant configurations, and thus GTL plant efficiencies will be site specific, commercially driven decisions.

S-2 can be produced economically in a variety of plant configurations and sizes depending on the gas source, site conditions, and the proximity of the plant to its intended fuel market. For example, the smaller plants are ideal in situations where oil cannot be produced without flaring or venting the associated (co-produced) natural gas. In these situations plants can be configured to produce as little as 1,000 barrels per day ("bpd"). Larger plants, producing 5,000 to 10,000 bpd, can be based on a variety of platforms designed for either land or marine use, constructed on site or erected from modular units. Fuel production trains of approximately 25,000 bpd have also been designed as components of 100,000 bpd and larger GTL complexes.

Mobile marine designs are particularly suited for smaller fields located offshore or in coastal delta areas that can operate over periods of 5 to 10 years until gas production diminishes, at which time the GTL plant would be moved to a new source of gas. Syntroleum GTL plants can be incorporated into the design of Floating Production Storage and Offloading ("FPSO") used in the development and commercialization of large offshore projects located in deep water and at distances too far from gas markets for gas pipelines to be economical. One such deep-water example is the United States Gulf of Mexico.

Depending upon plant size, configuration, and the suite of products co-produced, S-2 can be produced and sold for \$0.80 - 1.50/gallon. As demand for S-2 increases and as larger dedicated plants are constructed over the next 3 to 5 years, this price is expected to decrease to \$0.50 – 0.70/gallon. Within the next decade, S-2 is anticipated to be widely available at prices that are competitive with those prices of Tier 2 compliant gasoline and diesel fuels.

III. MARKET INCENTIVES

Use of alternative fuel grew at an annual rate of over 10% a year, whereas use of gasoline increased at a rate of only 1.6% a year.³ However, even with this high growth, alternative fuel use only amounts to about 0.2% of the fuel used in the United States transportation sector each year. This gap can be narrowed. Syntroleum anticipates that approval of S-2 as an alternative fuel will help narrow the gap between the use of alternative fuel and gasoline.

The replacement of conventional fuels with alternative fuels under EPAct has proven to be a daunting challenge. The primary stumbling blocks are (1) ready markets for the fuel (existing vehicles that can use the fuel), and (2) undeveloped distribution systems that hinder the availability of the fuel. S-2 fuel does not face either obstacle.

A. There Are Ready Markets for Syntroleum S-2 Fuel.

S-2 is backward compatible, meaning that it can operate in standard diesel engines. Accordingly, standard diesel vehicles provide a ready market for the fuel. Two advantages of this ready market are that: (1) consumers can purchase cleaner fuel without having to buy a new vehicle, and (2) the environment instantaneously benefits because consumers can use cleaner fuel without having to wait for the development of engine technologies compatible with a new alternative fuel.

Moreover, as engine technology develops, the market for S-2 will expand because S-2 is technology neutral. In other words, S-2 can operate in innovative engines as well as current production model diesel engines and vehicles.⁴ S-2's versatility is due to its high purity, compositional uniformity, compatibility with existing additive packages, and high hydrogen density.

The fuel cell, for example, is one of the most promising new power sources, and it presents a future potential market for S-2. S-2 is an ideal fuel cell fuel because it contains no measurable sulfur, aromatics, olefins or metals. Further, hydrogen yield per unit volume of fuel (as supplied to the fuel cell from a fuel cell fuel processor) using S-2 is roughly double that of other fuel cell fuels under consideration, and it can be transported as a liquid through the existing fuel distribution system. S-2 is likely to be more economical, structurally practical, and environmentally benign than conventional gasoline and diesel, which have also been tested in fuel cells. Recognizing S-2's potential, IdaTech Corp (formerly Northwest Power Systems), a leading manufacturer of fuel cell components and systems, certified S-2 as an effective on-board source of hydrogen to power its fuel cells in early February 2000.⁵

³ Use of alternative fuels has increased from 230 thousand gasoline equivalent gallons ("gegs") in 1992 to an estimated 351 thousand geegs in 1999. (Table D, Attachment 4).

⁴ As discussed in Section VII, S-2 fuel has performed well as a diesel fuel in numerous tests in a variety of engines.

⁵ *Northwest Power Certifies Syntroleum Fuels in Fuel Cell Reformers*, Syntroleum Corp., (Feb. 2, 2000), www.syntroleum.com.

The primary advantage of S-2's technology neutrality is that it encourages further innovation in engines. Consumers will not buy expensive new vehicles if there is a chance that the fuel required will be inconvenient or unavailable. Therefore, automobile manufacturers are reluctant to risk huge investments in new engines and vehicles without a reasonable expectation of adequate fuel supplies at an affordable cost. In short, concerns about potential market demand that accompany investment in new engine technologies are significantly reduced when there is a widely available compatible fuel.

B. S-2 Is Compatible with Existing Distribution Systems.

Syntroleum anticipates that the introduction and success of S-2 fuel as an alternative fuel to fleets covered under EPAct will lead to demand for S-2 fuel in the commercial sector. Demand for ultra-clean diesel fuel in the commercial sector is already escalating as engine and vehicle manufacturers begin to respond to the Environmental Protection Agency's ("EPA's") anticipated Tier 2 emission standards. For example, the traditional gasoline engines that power Sport Utility Vehicles ("SUVs") and full size pick-up trucks are expected to be replaced with cleaner and more efficient compression ignition direct injection ("CIDI") diesel engines. The current use of diesel engines in the light truck category, which includes SUVs and full size pick-up trucks, is about 5% and is growing at a rate of about 12% per year. This switch is significant because the light truck vehicle category is emerging as the dominant vehicle type in the United States, commanding 49% of the new-vehicle market in 1998.⁶ Moreover, the use of diesel fuel overall is already growing 3 times faster than that of gasoline (Table D, Attachment 4). Further, the Partnership of New Generation of Vehicles ("PNGV") has identified the CIDI diesel engine as the innovation with the greatest potential to achieve their stated goal of 80 miles per gallon ("mpg").⁷

Syntroleum does not expect distribution to present an obstacle to meeting the demand in the commercial sector. Distribution will be straightforward because S-2 is compatible with existing transportation vehicles, and other means of conveyance (e.g. ships, barges etc.), as well as existing tanks and pumps in service stations and fueling facilities. This has three clear advantages: (1) it allows consumers to maintain current behavior patterns, while using a new, cleaner technology; (2) it allows fuel distributors to become partners instead of adversaries of new technology; and (3) it eliminates the need for large investments in new fuel delivery systems (service stations, etc.)⁸

⁶ Ward's Motor Vehicle Facts & Figures (1999). Notably, the biggest factor in those increased truck sales was a 15% rise in sport utility vehicles ("SUVs"), giving SUVs a total market share of all cars and trucks of 17.5%.

⁷ Department of Energy ("DOE"), Office of Transportation Technologies, www.ott.doe.gov/oatt/enable_cidi.html.

⁸ This assumes that the Environmental Protection Agency ("EPA") establishes a single specification diesel fuel for on road use.

IV. LEGAL STANDARD FOR THE DESIGNATION OF AN ALTERNATIVE FUEL

Section 301(2) of EPAct, defines the term “alternative fuel” as:

methanol, denatured ethanol and other alcohols; mixtures containing 85 percent or more (or such other percentage, but not less than 70 percent, as determined by the Secretary, by rule, to provide for requirements relating to cold start, safety, or vehicle function) by volume of methanol, denatured ethanol, and other alcohols with gasoline or other fuels; natural gas; liquefied petroleum gas; hydrogen; coal-derived liquid fuels; fuels (other than alcohol) derived from biological materials; electricity (including electricity from solar energy); and any other fuel the Secretary determines, by rule, is substantially not petroleum and would yield substantial energy security benefits and substantial environmental benefits.

42 U.S.C.A. § 13211(2) (West 1999).⁹

Accordingly, to deem S-2 fuel an alternative fuel, the Secretary must examine whether S-2 fuel: (1) is substantially not petroleum, (2) would yield substantial energy security benefits, and (3) would yield substantial environmental benefits. *See id.* § 13211(2). For the reasons explained below, S-2 should be deemed an alternative fuel, as a matter of law, because it meets all three criteria.

⁹ Syntroleum is also petitioning the DOE to deem S-2 (or all synthetic paraffin diesel with the properties of S-2) a “replacement fuel” when S-2 is blended with other motor fuels. Section 301(14) of EPAct defines the term “replacement fuel” as: “the portion of any motor fuel that is methanol, ethanol, or other alcohols, natural gas, liquefied petroleum gas, hydrogen, coal derived liquid fuels, fuels (other than alcohol) derived from biological materials, electricity (including electricity from solar energy), ethers, or any other fuel the Secretary determines, by rule, is substantially not petroleum and would yield substantial energy security benefits and substantial environmental benefits.” 42 U.S.C.A. § 13211(14) (West 1999). The definitions of “alternative fuel” and “replacement fuel” suggest that when the DOE deems a fuel an “alternative fuel,” any portion of that “alternative fuel” in a motor fuel would automatically qualify as a “replacement fuel.” If such qualification as a “replacement fuel” is not automatic, Syntroleum wishes to make it clear that it is also petitioning the DOE to deem S-2 that is blended with another motor fuel a “replacement fuel.”

V. CRITERION ONE: SUBSTANTIALLY NOT PETROLEUM

A. Syntroleum S-2 Fuel Is Produced Solely from Natural Gas or Flared Gas and Is 100% Non-Petroleum.

First, Section 301(2) of EPAct provides that the Secretary may deem a fuel an alternative fuel only if the fuel is substantially not petroleum. *See* 42 U.S.C.A. § 13211 (2) (West 1999). S-2 fuel is produced from natural gas, flared gas (also includes vented gas)¹⁰, and/or other methane rich gas streams utilizing the Syntroleum Process, and is 100% non-petroleum.

The initial (raw) products of the Syntroleum Process are liquid hydrocarbons and water. Simple and conventional refining processes are then used to separate and upgrade the hydrocarbons into S-2 fuel, which meets the product specifications contained in Table 1.

At present, Syntroleum is requesting that S-2 fuel be designated as an alternative fuel, intended for direct use as a neat fuel for use in compression ignition engines and/or fuel cells. As such, 100% of its Btu content is non-petroleum. Nonetheless, Syntroleum recognizes that the use of S-2 fuel in blends with conventional diesel could offer marked improvements in regulated emissions and help the United States refining industry meet the anticipated phase-in of lower sulfur specifications for diesel fuel under Tier 2 standards. Therefore, Syntroleum anticipates seeking the designation of S-2 blends as alternative fuels in the near future.

B. Physical and Chemical Characteristics of S-2 Fuel

S-2 is a highly paraffinic, high-cetane distillate product suitable for conventional and advanced compression ignition engines, as well as fuel cells. S-2 is physically similar to petroleum-based diesel fuels, but with superior combustion emission characteristics. Comparisons of key physical properties are shown in Table 1. At ambient temperature and pressure, S-2 is a colorless, stable, environmentally safe liquid that can be shipped, stored, and dispensed using the same fuel distribution and handling procedures as petroleum diesel. Its volatility properties are the same as those for EPA #2 diesel. S-2 does not contain any measurable olefins, metals, aromatics or alcohols.

¹⁰ Vented gas generally consists of methane and other minor gases, including ethane, propane, CO₂, and nitrogen.

Table 1. Comparison of Physical and Chemical Properties

Property	Test Method	Units	Syntroleum S-2	EPA # 2 Diesel
Specific gravity	ASTM D - 1298		0.771	0.846

\a\ N/D - Not Detectable

\b\ N/A - Not Applicable

VI. CRITERION TWO: SUBSTANTIAL ENERGY SECURITY BENEFITS

Second, Section 301(2) of EPAct provides that the Secretary may deem a fuel an alternative fuel only if the fuel has substantial energy security benefits. *See* 42 U.S.C.A. § 13211 (2) (West 1999). This criterion reflects the government's well-founded concern that the United States relies too heavily on imported oil, which is the feedstock for petroleum-based fuels. One way to reduce the United States' reliance on imported oil in the near future is to diversify the United States' transportation energy sources.

Based on Energy Information Agency ("EIA") data, overall demand for petroleum in the United States is expected to increase at a rate of 1.2% per year, while the United States' domestic production of petroleum is expected to decline at a rate of 1.1% per year. The EIA predicts that this imbalance will result in the increase of oil imports of 2.3% per year.

The transportation sector is in large part responsible for the increase in fuel demand. In 1997, for example, the transportation sector consumed 26% of the energy used in the United States, 97% of that was petroleum-based. Moreover, the EIA predicts that by 2010 the transportation sector will consume over 30% of energy used in the United States, with its consumption of petroleum-based fuels growing proportionally.¹¹ Because the transportation sector is such a major player, it could significantly reduce the United States' reliance on imported oil by simply diversifying its energy sources.

In furtherance of this goal, S-2 fuel, which is produced from natural gas, is a logical substitute for petroleum-based fuels in the transportation sector because: (1) the United States has plentiful natural gas resources, (2) numerous countries, in addition to members of OPEC, have plentiful natural gas resources, (3) S-2's full fuel-cycle is potentially more energy efficient than the full fuel-cycle for reformulated diesel ("RFD")¹² or reformulated gasoline ("RFG"), and (4) S-2's full fuel-cycle uses substantially less petroleum than either RFD or RFG.

¹¹ *Annual Energy Outlook 1999 with Projections to 2020*, DOE/ Energy Information Agency ("EIA"), Office of Integrated Analysis and Forecasting; EIA-0383(99), (Dec. 1998), DOE, www.eia.doe.gov/pub/pdf/multi.fuel/038399.pdf.

¹² Unless otherwise noted, reformulated diesel ("RFD") refers to a reformulated diesel fuel having 15 parts per million ("ppm") sulfur.

A. Syntroleum S-2 Fuel Can Reduce Reliance on Imported Oil Because It Can Utilize the United States' Natural Gas Resources.

As described above, S-2 fuel is 100% non-petroleum. The Syntroleum Process converts natural gas into S-2, using a patented GTL technology based on FT chemistry. The feedstock to this process can be anything from pipeline quality natural gas to methane rich gas streams containing up to 30% inert gases including nitrogen and carbon dioxide.¹³

The United States has plentiful natural gas resources. Currently, it is estimated that the United States has a reserve of 164 trillion cubic feet ("tcf"). The United States has a very sophisticated production, collection, and distribution system for delivering gas to a well-developed market. However, not all of this gas reaches the final market. In 1997, of the total United States natural gas production of 24.2 tcf, 3.50 tcf was re-injected and 0.26 tcf was vented or flared (Table B, Attachment 4). If this vented or flared gas were to be converted using the Syntroleum Process, over 800 million gasoline equivalent gallons ("gegs") of S-2 could be potentially produced. Just 1% of this amount (8 million geogs) is greater than either the total amount of alcohol based fuels used as alternative fuels in 1999 (5.5 million geogs), or the total amount of liquefied natural gas ("LNG") (6.9 million geogs) used during the same period (Table D, Attachment 4).¹⁴ Viewed another way, 800 million geogs of S-2 is more than twice the total amount of alternative fuel consumed in 1999 (325 million geogs).¹⁵

In addition to the traditional sources of United States natural gas, there are other gas reserves that have not been tapped. The Gas Research Institute ("GRI") has reported that the deepwater Gulf of Mexico is poised for a major increase in production over the next 5 to 10 years, and gas from this area will soon represent a substantial percentage of all oil and gas production in the lower-48 states.¹⁶ Current deepwater (water depths up to 1000 meters) discoveries in this region are placed at 40 tcf, with estimates of undiscovered potential reserves ranging from 68 tcf to 217 tcf. However, the depth and distance from shore will make commercialization of these vast amounts of gas difficult. With GTL plants placed on FPSOs, the natural gas could be converted to GTL fuels that could be easily transported to shore in conventional barges or tankers. These FPSOs could be either permanent facilities or used on a temporary basis while awaiting the development of a gas gathering and pipeline system to bring the gas production to shore. GTL-capable FPSOs could accelerate development of deepwater oil fields.

¹³ See *supra*, note 2.

¹⁴ *Alternatives to Traditional Transportation Fuels*, DOE/EIA, (Jan. 2000), http://www.eia.doe.gov/cneaf/solar.renewables/alt_trans_fuel98/atf_99.html.

¹⁵ See *id.*

¹⁶ *Changing Perceptions of Remaining U.S. Conventional Gas Resources*, Gas Research Institute ("GRI"), Gas Issues and Trends, (Oct. 1998).

Stranded gas reserves have presented other difficulties. By definition, stranded gas reserves have little or no market prospect. However, GTL technology has suddenly brought stranded gas reserves within economic reach.¹⁷ In Prudhoe Bay, Alaska, 25 to 30 tcf of natural gas that has been stranded under the Northern Slope suddenly has market prospects. If these reserves were tapped, and the natural gas was converted to liquid fuels, 2.5 to 3.0 billion barrels of ultra-clean fuels (an amount roughly equal to 10% of current United States reserves) could be produced and thus displace foreign fuel imports on a barrel for barrel basis.

Prior to consideration of GTL as an option, commercialization of these Alaskan reserves (as natural gas), required a significant investment in infrastructure. In addition to recovery and processing facilities, a new 800-mile gas pipeline and LNG complex was required to bring the natural gas to markets in the northwest. But now, with GTL technology, this gas can be produced and processed on site and pumped down the existing pipeline as either "synthetic crude" or segregated GTL product. The addition of GTL oil to the Trans Alaska Pipeline would have several additional benefits beyond the increased availability of GTL fuels to the United States. The additional pipeline throughput should reduce tariff increases that are anticipated as Alaskan North Slope production matures and declines. Moreover, GTL production would extend the economic life of the Trans Alaska Pipeline, and permit the production of oil that would have otherwise stayed in the ground. The DOE's recognition of S-2 as an alternative fuel will facilitate efforts to mobilize investment to economically capture stranded gas reserves on the North Slope of Alaska.

In addition to the conversion of gas now flared and vented, the Syntroleum Process enables sources of sub-quality natural gas to be tapped, as well. A 1996 GRI study found that 41% of proven reserves in the United States are "sub-quality" gas.¹⁸ The GRI defines "sub-quality" as gas having nitrogen and/or carbon dioxide and/or hydrogen sulfide in excess of average pipeline limits of 4%, 2% and 4 parts per million ("ppm"), respectively. Not all sub-quality gas streams are suitable for conversion into liquid fuels because of their high sulfur content. Nevertheless, the Syntroleum Process can utilize 60% of the sub-quality gas streams identified in the GRI report that contain only nitrogen and/or carbon dioxide.¹⁹

Other sources of natural gas suitable for conversion into liquid transportation fuels are coal-bed methane, landfill methane, and ocean-bed methane hydrates. There is an estimated 275 to 649 tcf of recoverable coal bed methane in the United States, at least 4 times the current United States proven gas reserves. For safety reasons, much of this gas is vented into the atmosphere. Although some coal bed gas is recovered and sold

¹⁸ *Chemical Composition of Discovered and Undiscovered Natural Gas in the Continental United States*, GRI, (June 1999).

¹⁹ See *supra*, note 2.

via pipelines, much of it is not. Some of these valuable resources could be recovered and converted into S-2 using the Syntroleum Process.

Moreover, landfills are the single largest anthropogenic source of methane emissions in the United States.²⁰ EPA estimates that 3,000 to 6,000 landfills in the United States currently produce gases containing methane, representing 600 bcf of methane per year, only 15% of which is recovered.²¹ Of these landfills, more than 500 are capable of generating sufficient quantities of gas to support compact, mobile Syntroleum process plants to produce S-2. Once plant designs have been perfected for these smaller applications, S-2 will be able to be produced from other anthropogenic sources of methane and bio-mass.

Further, and on a much larger scale, there are vast deposits of methane hydrates (methane molecules trapped in ice) in the United States in permafrost regions and beneath the ocean floor. A 1995 United States geological survey assessment places a mean estimate of United States gas hydrates at 320,000 tcf, a number 20 times the optimistic estimate of remaining world reserves of conventional natural gas.²² Although there is currently no proven means of economically recovering methane hydrates today, Syntroleum has recently been granted a United States patent for a system that recovers gas from ocean-bed methane hydrates and converts it into liquid fuels via floating GTL processing plants. Accordingly, Syntroleum is optimistic that methane hydrates will become an economically viable feedstock for S-2 production in the future.

B. Syntroleum S-2 Fuel Can Reduce Reliance on Imported Oil Because It Can Utilize Natural Gas In Foreign Countries, Other Than OPEC.

Although the United States natural gas resources are plentiful, the United States houses only 3 to 4% of the world's proven reserves of gas. By various estimates, there are 5,000 to 15,000 tcf of stranded gas resources in the world and even larger amounts of associated gas. West Africa, for example, provides almost 2% of the world's gas, but 60-70% of it is flared. Producing gas from foreign sources, such as West Africa, is economical. One study, which calculated the cost of producing gas from associated and dissolved gas fields located in major production areas in the world, reported that 6 of the fields it sampled have a combined annual production capacity of 290 bcf and are capable of producing 1.2 billion gallons of GTL fuel per year at a gas cost of less than \$1.00/mcf.²³

²⁰ See <http://www.epa.gov/oppeoee1/globalwarming/emissions/national/methane.html>.

²¹ See *id.*

²³ Greene, D.L., *An Assessment of Energy and Environmental Issues Related to the Use of Gas-to-Liquid Fuels in Transportation*, (Nov. 1999), www-cta.ornl.gov/publications/ornl-tm-1999-258.pdf.

Notably, even if GTL fuels, such as S-2, were produced outside of the United States, our reliance on oil imports would be reduced, and indeed, the market power of OPEC would be reduced. As part of a study for the DOE, D.L. Greene of the Oak Ridge National Laboratory examined in detail the impact on United States' energy security of GTL fuels being produced outside of the United States.²⁴ Based on his study, Greene concluded that because GTL fuels are a direct substitute for imported oil, the emergence of a GTL industry abroad could reduce the United States' oil imports, and in turn, reduce OPEC's market power. In essence, a GTL industry abroad could become a formidable OPEC competitor. Such a competitor may diminish OPEC's ability to raise oil prices from \$18 a barrel to \$30 a barrel on a whim, as OPEC did in the first quarter of the year 2000.

C. Syntroleum S-2 Fuel Is a Logical Substitute for Petroleum-Based Fuels Because Its Full Fuel-Cycle Is Potentially More Efficient than the Full Fuel-Cycle for RFD and RFG.

M. L. Wang and H. S. Huang of the Argonne National Laboratory developed a model to estimate the full fuel-cycle energy and emission impacts of conventional and alternative fuels, including FT diesels such as S-2, produced from natural gas and flared gas feedstocks. This model is known as the Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation ("GREET") model.²⁵ The GREET full fuel-cycle uses the following three stages of the fuel-cycle to evaluate energy use and emissions: (1) feedstock production, including transportation to fuel production facilities, (2) fuel production, including transportation and distribution to fueling locations, and (3) vehicle operation.

Using the GREET model, Syntroleum compared the full fuel-cycle energy efficiency (as well as GHG emissions) of S-2 produced from natural gas (gas delivered through a distribution infrastructure that serves a market) and flared gas to the full fuel-cycle energy efficiency of RFG and GREET reformulated diesel ("GREET Reformulated Diesel"). The GREET model takes into account the energy required to lower the sulfur levels of gasoline and diesel to 30 ppm and 50 ppm, respectively. However, EPA has announced that it will set Tier 2 diesel fuel sulfur specification at 15 ppm.²⁶ Therefore, S-2 should be compared to diesel fuel with a sulfur level of 15 ppm. In other words, the total energy required and GHG emissions produced during the sulfur removal and hydrotreating process must be taken into consideration. Accordingly, Syntroleum calculated the energy and hydrogen required to lower the sulfur level of

²⁴ See *id.*

²⁶ *EPA Proposes Cutting Sulfur in Diesel Fuel; Lowering Truck Emissions*, Daily Report for Executives (BNA), May 18, 2000.

GREET Reformulated Diesel from 50 ppm to 15 ppm, referred to herein as RFD. Then, Syntroleum combined the result with the GREET model to compare total energy and emissions. The results of those calculations and the process parameters are shown in Attachment 3. The energy requirements for the production of S-2 during each phase of the full fuel-cycle are shown in Table 2 below.

Table 2 - Total Energy – Btu/mi

	Feed	Fuel	Vehicle	Total
S-2 from Natural gas	319	4,897	5,116	10,331
S-2 from Flared gas	319	-4,666	5,116	769
RFD \a\	185	1,036	5,060	6,281
RFG	266	1,606	7290	9,162

\a\ GREET model energy plus energy required to produce 15 ppm RFD

When S-2 fuel is produced from flared gas its full fuel-cycle is 88% and 92% more energy efficient than RFD and RFG, respectively. Energy that would otherwise be wasted as gas is flared and can be converted into clean S-2 with lower emissions than either of the two comparative fuels. The possibilities for S-2 to be made from flared gas are numerous. As mentioned above, in 1997, the United States alone produced 0.26 tcf of vented or flared gas, which could produce 800 million gregs of S-2. Moreover, over 10 times that amount of gas was flared worldwide. The gas flared worldwide could produce an amount of S-2 equal to 33% of all the diesel fuel consumed for transportation use in the United States each year.

However, not all of the S-2 can be made from flared gas.²⁷ Although many factors can influence the mix between the two sources of feedstock gas, project economics will be a critical factor. In many circumstances where gas is flared, its cost will be lower than the cost of natural gas produced for market. The critical economic role of feedstock gas prices will drive GTL project development towards flared gas.

Figure 1, below, illustrates that using just a small percentage of flared gas as an S-2 feedstock makes S-2 as energy efficient as, if not more energy efficient than, RFG or RFD.

²⁷ See *infra*, discussion at Section VII.B.2. (discussing the use of flared gas as a feedstock and its impact on GHG emissions).

Depending upon the fuel it displaces, the percent of flared gas used as a feedstock that is required to make S-2 energy “neutral” ranges from 10 to 40%. Any amount of flared gas over those percentages would result in net energy savings, as discussed above.

D. Syntroleum S-2 Fuel's Full Fuel-Cycle Uses Substantially Less Petroleum than RFD and RFG, Regardless of Whether It Is Produced From Natural Gas or Flared Gas.

As shown in Table 3, below, when S-2 fuel is produced from either natural gas or flared gas, the full fuel-cycle petroleum use is 96% and 97% less than the full fuel-cycle petroleum use of RFD and RFG, respectively.

Table 3 - GREET Full Fuel-Cycle Petroleum Use – Btu/mi

	Feed	Fuel	Vehicle	Total
S-2 from Natural gas	23	168	0	191
S-2 from Flared gas	23	165	0	188
RFD \a\	48	462	5,060	5,571
RFG	69	661	6,397	7,127

\a\ GREET Model petroleum use plus petroleum required to produce 15 ppm RFD

Moreover, S-2 has a carbon ratio of 85% (by weight) and a lower heating value (“LHV”) of 121,600 Btu/gallon, making one gallon of S-2 used in a vehicle equivalent to 1.08 gallons of gasoline on an energy equivalent basis. Thus, S-2 use reduces petroleum use during vehicle operation. Efficiencies of diesel and gasoline full fuel-cycles are compared in more detail in Section VII.

VII. CRITERION THREE: SUBSTANTIAL ENVIRONMENTAL BENEFITS

Finally, Section 301(2) of EPAct provides that the Secretary may deem a fuel an alternative fuel only if use of the fuel has substantial environmental benefits. *See* 42 U.S.C.A. § 13211(2) (West 1999). S-2 meets this criterion for the reasons explained below.

A. Emission Reductions in Criteria Pollutants, Nitrous Oxide, and Air Toxics

S-2 fuel is an ultra clean liquid fuel with highly desirable properties for reducing emissions in diesel engines. Some of its attributes are:

- High cetane number
- No detectable sulfur
- No detectable aromatics
- Low density and high hydrogen content

Numerous studies have shown that FT diesel fuels with these attributes reduce emissions and perform well in diesel engines.²⁸ Explanations for the reduction of PM by synthetic paraffin diesel include the absence of sulfur and the high fuel hydrogen to carbon ratio (non-detectable aromatics). Its high cetane may assist in the reduction of CO, HCs, and aldehyde emissions, and its low aromatic content appears to reduce air toxins. Related properties of S-2 and similar FT fuels, which include lower fuel density, high hydrogen content, and high cetane may reduce flame temperature, and thereby reduce NO_x production.

Syntroleum tested S-2 fuel independently, at Southwest Research Institute (“SwRI”), against conventional EPA #2 diesel, California CARB specification diesel fuel, and Swedish City diesel fuel. Based upon the attributes discussed above, CARB diesel fuel and Swedish City diesel fuel are the cleanest diesel fuels commercially available today. Table 4, below, compares the specifications of these fuels as tested to S-2.

²⁸ See, e.g., T.W. Ryan, *Emission Performance of Fischer-Tropsch Diesel Fuels: Gas to Liquid Processing*, Intertech Conference, (1999); T.W. Ryan, III and D. Montalvo, *Emissions and Performance of Fischer-Tropsch Diesel Fuels in a Modern Heavy Duty Diesel Engine* (1997); P.W. Schaberg et al., *Diesel Exhaust Emissions Using Sasol Slurry Phase Distillate Process Fuels*, SAE Technical Paper 972898 (1997); P. Cetane Number	74	47	51	52

SwRI performed a series of tests in a 5.9-liter Cummins heavy-duty diesel engine on an engine dynamometer to compare S-2 fuel's emissions of criteria pollutants,²⁹ air toxics, and nitrous oxide ("N₂O"), to these other diesel fuels. SwRI also performed a series of tests using the same engine in a Dodge RAM 2500 HD Quad Cab SLT on a chassis dynamometer and a 1.9-liter light-duty diesel engine in a 1999 Volkswagen Golf GL TDI on a chassis dynamometer. Emissions data acquired during these tests are attached as Appendices A-L. Summaries of the SwRI test results are presented in Attachment 1.

SwRI's results, using the engine dynamometer tests and the chassis dynamometer tests, for the Cummings engine were so similar that, for purposes of comparing S-2 emissions to other diesels in this section, reference will only be made to the heavy-duty engine testing (on an engine dynamometer). However, later when Syntroleum compares S-2 to RFD using the GREET model, it cites emission results from the chassis tests for the Dodge RAM in order to be consistent with the model's LDT2 vehicle.³⁰ In addition, Syntroleum cites the test results for the Volkswagen equipped with exhaust emission control devices in its discussion of the enabling benefits of S-2 on after treatment devices.

1. Emission Reductions of Criteria Pollutants, Nitrous Oxide, and Air Toxics – the SwRI Engine Tests

a. Criteria Pollutants

(i) Tier 1 Emissions Standards

At the outset, it is notable that S-2 met or exceeded the applicable EPA Tier 1 emissions standards appropriate for each test platform according to the year of manufacture and vehicle category. For the engine tests, the applicable protocol was the EPA transient test. For the chassis tests, the applicable protocol for measuring criteria pollutants is EPA's Federal Test Procedure ("FTP"), or the city protocol, whereas EPA's Highway Fuel Economy Test ("HFET"), or the highway protocol, is used for fuel economy

²⁹ Criteria pollutants are listed pursuant to Section 108 of the Clean Air Act ("CAA"), and include particulate matter ("PM"), sulfur dioxide ("SO₂"), nitrogen oxides ("NO_x"), carbon monoxide ("CO"), volatile organic compounds ("VOCs")/ ozone, and lead ("Pb"). See 40 C.F.R. pt. 50 (1999). (Hydrocarbon ("HC")) is frequently considered a criteria pollutant because it contributes to the formation of ozone). The term "criteria pollutants," as used herein, refers to any combination of these pollutants.

³⁰ The vehicle tested had a curb weight of 6,250 pounds consistent with the GREET category LDT2 vehicle (GVW between 6,001 and 8,500 pounds).

standards. The Aggressive Driving Test Protocol ("US06") is an addendum to the FTP protocol.

Table 5. EPA Emissions for Heavy-duty Engine \a

Test	Emissions Results, g/bhp-hr

S-2	0.03	0.02	0.10	0.78	0.03

\a\ 1999 Volkswagen Golf GL TDI with a 1.9 L diesel engine on a chassis dynamometer.

(ii) Relative Emissions Performance v. Test Fuel

The SwRI tests revealed that S-2's emissions of criteria pollutants are significantly lower than each of the other fuels tested. Table 8 shows the results of those tests and Figures 2 through 5 illustrate the percent change in S-2 emissions for each criteria pollutant.

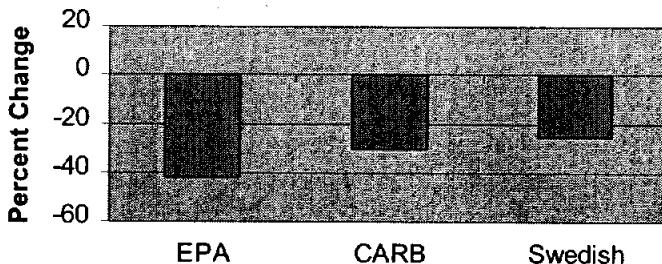

Table 8. Criteria Pollutants \a

	Measured Emission, g/bhp-hr \b\			
	HC	CO	NOx	PM
EPA #2 Diesel	0.12	1.2	4.0	0.10
CARB Diesel	0.09	1.1	3.7	0.08
Swedish City Diesel	0.09	1.2	3.6	0.08
S-2	0.07	0.8	3.2	0.06

\a\ Heavy-duty engine tests

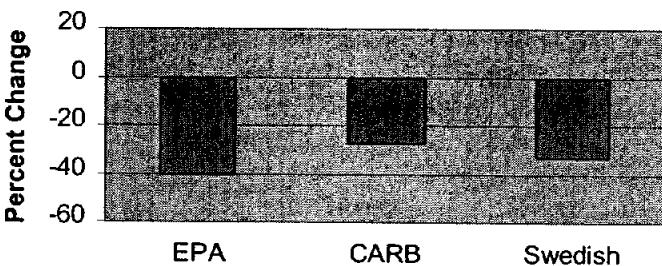

\b\ Some rounding in reported results

Figure 2. Percent Change in HC Emissions

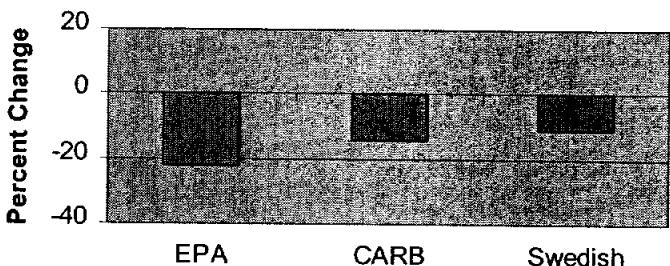

The results of the SwRI tests indicate that the HC emissions are reduced by 42% compared to EPA # 2 diesel, 30% compared to CARB diesel, and 25% compared to Swedish City diesel.

Figure 3. Percent Change in CO Emissions

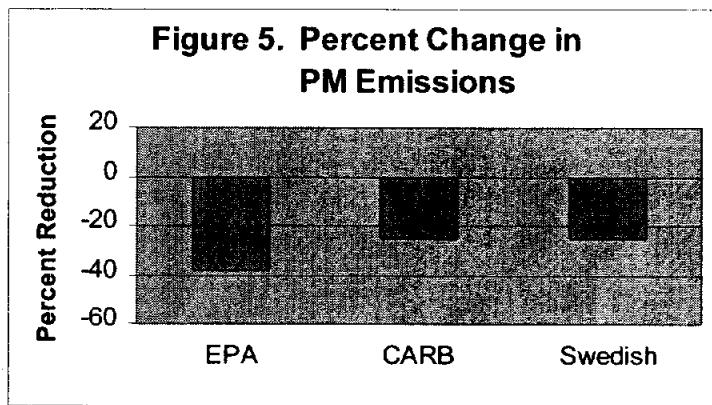

The results of the SwRI tests indicate that the CO emissions are reduced by 40% compared to EPA #2 diesel, 27% compared to CARB diesel, and 33% compared to Swedish City diesel.

Figure 4. Percent Change in NOx Emissions

The results of the SwRI tests indicate that the NO_x emissions are reduced by 22% compared to EPA #2 diesel, 14% compared to CARB diesel, and 11% compared to Swedish City diesel.

The results of the SwRI tests indicate that the PM emissions are reduced by 38% compared to EPA diesel, 25% compared to CARB diesel, and 25% compared to Swedish City diesel.

These tests indicate that S-2's emissions of criteria pollutants are significantly lower than the ultra low sulfur Swedish City diesel. This is particularly relevant because the sulfur level of Swedish City diesel (<1 ppm) is more than an order of magnitude lower than the 15 ppm, the proposed Tier 2 diesel fuel standard.

Additionally, the World-Wide Fuel Charter recommends that diesel fuel for "markets with further advanced requirements for emission control, to enable sophisticated NO_x and PM after treatment technologies" should be sulfur free, like S-2.³¹

b. Air Toxics and Nitrous Oxide

The SwRI tests reveal that S-2 fuel's emissions of air toxics and N₂O are considerably better than emissions of EPA #2 diesel, CARB diesel, and Swedish City diesel. In order for these tests to be compatible with criteria emissions discussed above, the heavy-duty engine tests are shown in Table 9. Tests for air toxics and N₂O were also conducted for heavy light-duty and light-duty vehicles. The results of these tests are appended in Attachment 1. Figures 6 and 7 illustrate the percent change in S-2 emissions for air toxics and N₂O, respectively.

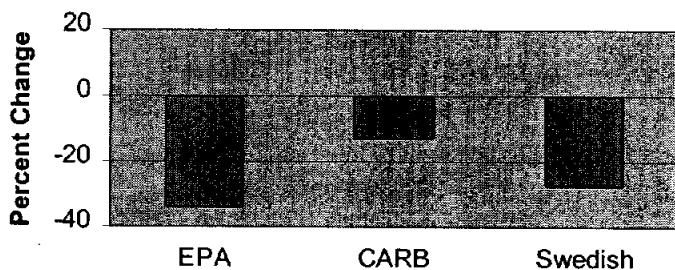

³¹ European Automobile Manufacturers Association, Alliance of Automobile Manufacturers, Engine Manufacturers Association and the Japan Automobile Manufacturers Association, World-Wide Fuel Charter, (Apr. 2000), <http://www.acea.be/acea/WWFCharter042000.pdf>.

Table 9. Air Toxics and Nitrous Oxide \a

	Measured Emission, mg/bhp-hr	
	Air Toxics	N ₂ O
EPA #2 Diesel	23.8	7.1
CARB Diesel	17.9	5.9
Swedish City Diesel	21.5	5.4
S-2	15.6	5.0

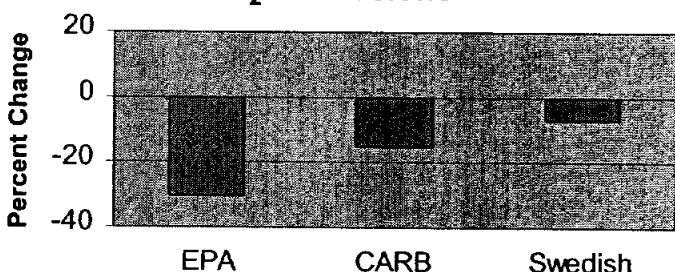

\a\ Heavy Duty engine tests

Figure 6. Percent Change in Air Toxics Emissions

The results of the SwRI tests indicate that the air toxic emissions are reduced by 34% compared to EPA #2 diesel, 13% compared to CARB diesel, and 27% compared to Swedish City diesel. Aldehyde and ketone emissions, also determined as part of the HC speciation, show very similar reductions.

Figure 7. Percent Change in N₂O Emissions

The results of the SwRI tests indicate that the N₂O emissions are reduced by 30% compared to EPA diesel, 15% compared to CARB diesel, and 7% compared to Swedish City diesel.

2. Reduction in Total Full Fuel-Cycle Emissions for Criteria Pollutants - GREET Model.

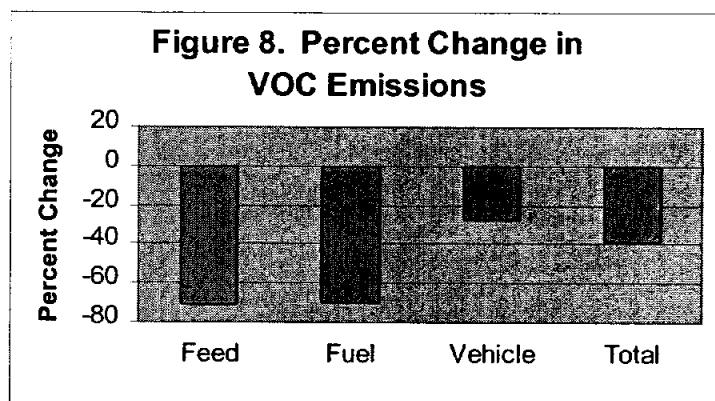

Full fuel-cycle emissions for S-2 (made from either non-flared or non-vented natural gas or from flared or vented gas) and RFD (15 ppm sulfur) were determined by adding the results from the GREET model to additional emissions determined by Syntroleum's analysis for RFD. Table 10, below, shows the emissions of the criteria pollutants for S-2 and RFD for the full fuel-cycle. Figures 8 through 12 illustrate the percent change in S-2 emissions for each pollutant during the feedstock production (including transportation), fuel production (including distribution), and vehicle operation phases of the full fuel-cycle.

Table 10. Full Fuel-Cycle Emissions

	Estimated Emission, g/mi				
	VOC	CO	NO _x	PM	SO _x
RFD \a\	0.16	5.77	0.37	0.06	0.09
S-2 \b\	0.10	4.08	0.29	0.04	0.02

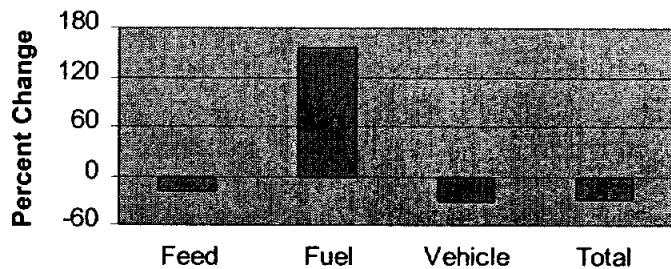

\a\ GREET model emissions plus emissions associated with production of 15 ppm RFD

\b\ Analysis for S-2 is based upon S-2 made from natural gas - either non-flared or non-vented gas or flared or vented gas. Full fuel cycle emissions for criteria pollutants from S-2 are consistent, regardless of whether the natural gas feedstock is vented or flared.

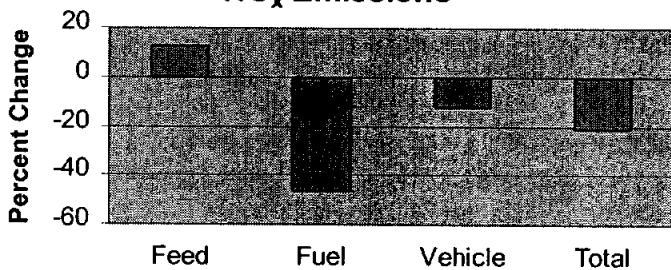

Reductions in VOCs are seen in all phases of the fuel-cycle, 71% during feedstock production, 70% during fuel production, and 27% during vehicle operation. S-2's total full fuel-cycle emissions of VOCs are 39% lower than those of RFD.

Figure 9. Percent Change in CO Emissions

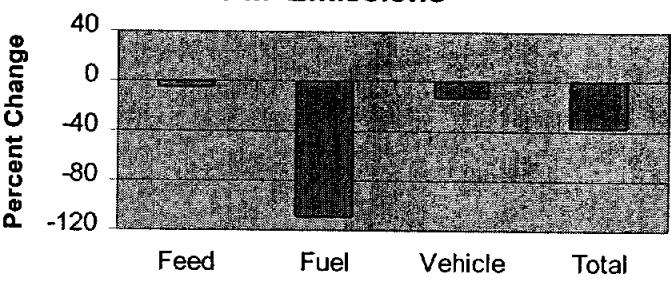

Reductions in CO emissions occur in two of the phases of the fuel-cycle, 18% during feedstock production and 31% during vehicle operation. Notwithstanding the increase in CO emissions during fuel production, the total full fuel-cycle reduction in S-2 emissions of CO compared to RFD is 29%.

Figure 10. Percent Change in NO_x Emissions

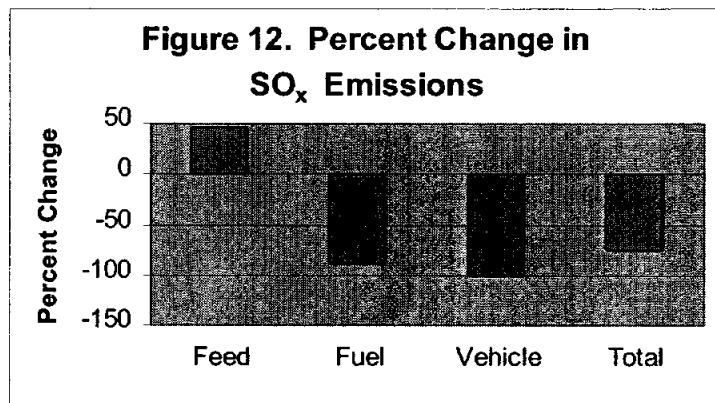

Reductions in NO_x are seen in two of the phases of the fuel-cycle, 46% during fuel production and 12% during vehicle operation. Notwithstanding the slight increase in NO_x emissions during feedstock production (which was attributed the use of fuels other than S-2 during the production phase), the total full fuel-cycle reduction in S-2 emissions of NO_x compared to RFD is 21%.

Figure 11. Percent Change in PM Emissions

Reductions in PM are observed in all phases of the fuel-cycle, 5% during feedstock production, 109% during fuel production, and 12% during vehicle operation. Total full fuel-cycle reduction in S-2 emissions of PM compared to RFD is 36%.

Reductions in sulfur oxides (“SO_x”) occur in two of the phases of the fuel-cycle, 89% during fuel production and 100% during vehicle operation. Notwithstanding the increase in NO_x emissions during feedstock production (which was attributed to the use of fuels other than S-2 during the production phase), the total full fuel-cycle reduction in S-2 emissions of SO_x compared to RFD is 75%.

B. Emission Reductions in Greenhouse Gases

1. Emission Reductions in Greenhouse Gases – the SwRI Engine Tests

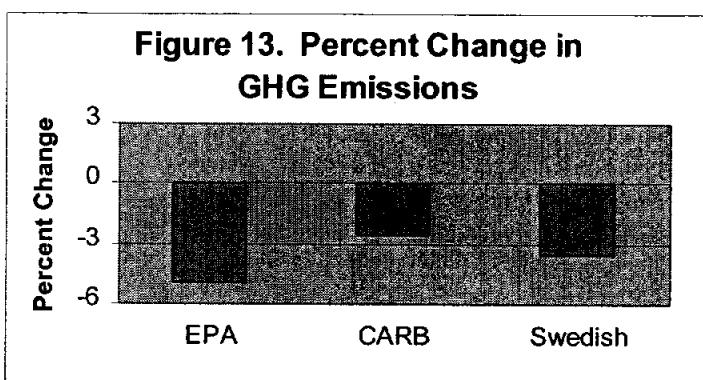

SwRI performed tests to compare the emissions of GHGs for S-2 to the test diesel fuels mentioned above. The GHGs measured included: carbon dioxide (“CO₂”), methane (“CH₄”), and N₂O. To evaluate total GHGs, the GREET model converted the emission rates for CH₄ and N₂O to the CO₂ equivalent based on the 100-year global warming potential (“GWP”) factors as cited by the Intergovernmental Panel on Climate Change. For example, the GWP conversion factors for CH₄ and N₂O were 21 and 310, respectively.

GHG emission tests were run on the Cummings 5.9 L engine as tested on an engine dynamometer and in the Dodge Ram on a chassis dynamometer and on the 1.9L Volkswagen on a chassis dynamometer. Table 11 summarizes the total GHG emission for the various fuels as tested in the Heavy Light-duty vehicle in a combination cycle representative of that used in the GREET model (55% FTP test and 45% HFET test). Results of the engine and light-duty vehicle tests are in the appendices. Figure 13 illustrates the comparative results between the fuels tested.

Table 11. SwRI Total GHGs \a

	Measured Emission, g/mi
EPA #2	487
CARB	475
Swedish	480
S-2	463

\a\ Heavy Light-duty vehicle, 55% FTP/ 45% HFET

The results of the SwRI tests indicate that the GHG emissions are reduced by 4.9% compared to EPA #2 diesel, 2.5% compared to CARB diesel, and 3.5% compared to Swedish City diesel. It should be noted that in all cases, the majority of the improvement was due to lower CO₂ emissions with the S-2 fuel. The CH₄ and N₂O combined to contribute less than 1% of the total GHG emissions measured.

2. Estimated Reduction in Total Full Fuel-Cycle Greenhouse Gases - the GREET Model

a. Preliminary Comparison Based on Syntroleum's Modified GREET Model

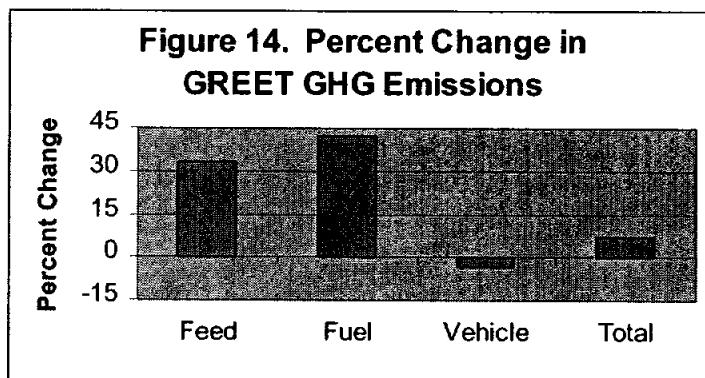

Full fuel-cycle emissions for S-2 (natural gas) and RFD (15 ppm sulfur) can be assessed by adding the results from the GREET model to additional emissions determined by Syntroleum's analysis for RFD. Table 12 shows the relative emissions of total GHGs during the feedstock production (including transportation), fuel production (including distribution), and vehicle operation phases of full fuel-cycle. Figure 14 illustrates the percent change in S-2 emissions for each of the three phases and the total GHGs.

Table 12. Full Fuel-Cycle GHG Emissions

	Estimated Emissions, g/mi			
	Feed	Fuel	Vehicle	Total
RFD \a\	27	93	405	525
S-2 \b\	37	132	393	561

\a\ GREET model emissions plus emissions associated with production of 15 ppm RFD

\b\ Analysis for S-2 is based upon an S-2 feedstock of natural gas from sources other than flared or vented gas.

A reduction of 3% in GHG emissions occurs during the vehicle operation phase of the fuel-cycle. Although there are increases during the feedstock production and the fuel production phases, these increases have a lesser impact because the bulk of the GHG emissions for all of the fuels are released during the vehicle operation phase. (See Table 12). Therefore, S-2's full fuel-cycle GHG emissions, in the preliminary comparison, are only 7% higher than those of RFD.

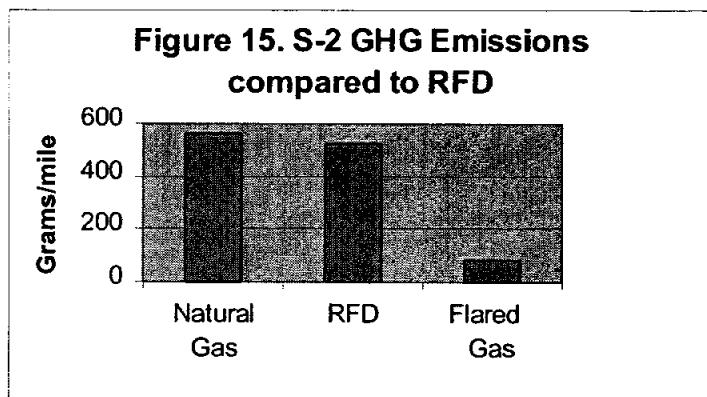

In summary, the preliminary GREET based comparison above suggests that S-2's total GHG emissions could be approximately 7% higher than those of RFD. However, this preliminary comparison does not take into account certain factors, which Syntroleum believes should be considered in a comprehensive comparison of GHG emissions. In particular, the preliminary GREET based comparison does not: (1) consider that S-2 will be produced from a combination of flared gas and pipeline quality natural gas on a worldwide basis; (2) consider the source of feedstock required to meet the increased demand for diesel fuel; and (3) consider that S-2 will displace RFG as well as RFD. Syntroleum believes that, if these three additional factors are taken into account in a comprehensive comparison of the GHG emissions, S-2's GHG emissions would be substantially equivalent to, if not lower than RFD's GHG emissions, and significantly lower than RFG's GHG emissions.

Syntroleum's reasons for believing that these three additional factors would lead to a more favorable comparison are set forth below.

b. Comprehensive Comparison Taking into Account Three Additional Factors

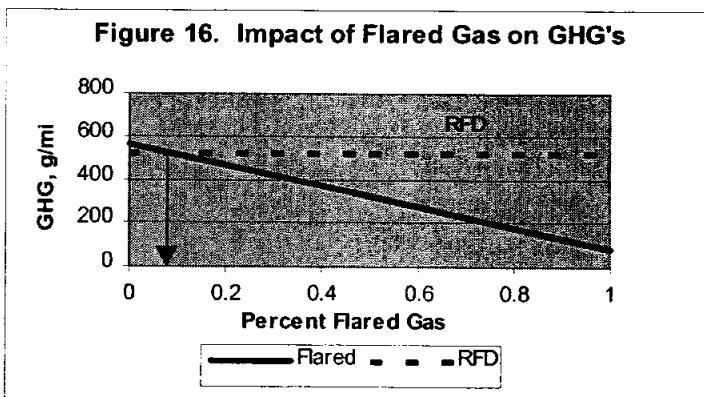

(i) Flared Gas

Comparing the full fuel-cycles of S-2, produced from 100% flared gas, to RFD reveals that S-2 has significantly lower GHG emissions, as well as significantly lower criteria pollutant emissions, than RFD. The most dramatic shift is in the fuel production phase of the fuel-cycle. Generally, when gas is flared, the energy of oxidation is lost and the carbon is dumped as CO₂ directly to the atmosphere. Figure 15 compares the total GHG emissions for S-2 produced from either natural gas or flared gas, to the total GHG emissions for RFD.

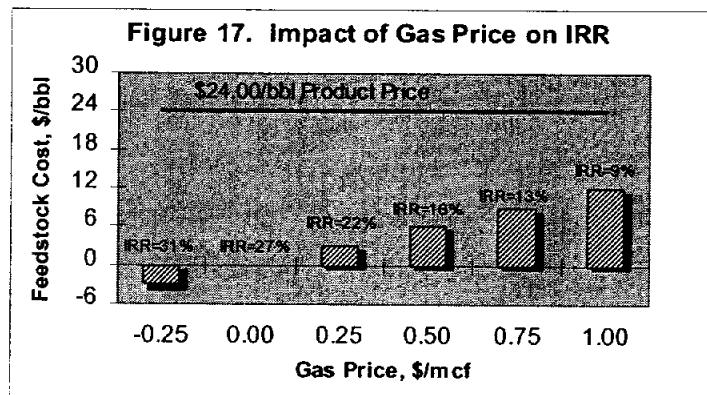

GHG emissions for S-2, produced from natural gas, are 558 grams per mile ("g/mi"), which is approximately 7% higher than the GHG emissions for RFD (525 g/mi). However, when S-2 is produced from flared gas, its GHG emissions are only 85 g/mi, which is 84% lower than GHG emissions for RFD. Moreover, when S-2 is produced from vented gas, the emissions reductions are even more significant because burned CH₄ has 21 times more impact on GHGs than combusted CH₄.

Figure 16, below, illustrates how increasing the percentage of flared gas used to produce S-2 can lower S-2's net GHG emissions, such that S-2's GHG emissions are equal to or lower than those of RFD.

Accordingly, if approximately 10% of S-2 were to be produced from flared gas, its GHG emissions would be equal to those of RFD. Moreover, if more than 10% of S-2 were produced from flared gas, then S-2's GHG emissions would actually be more environmentally beneficial than RFD.

For the most accurate comparison of S-2's GHG emissions to RFD's GHG emissions, the crucial question is - what percent of S-2 will be produced from flared gas? Although there is no easy answer, it is clear that economic viability of S-2 production is a critical factor. Plants will be built in areas where manufacturers can access gas cheaply. As currently designed, the Syntroleum Process plants can economically produce S-2 at a price similar to that of RFD from oil, assuming that natural gas feedstock costs hold steady at approximately \$1.00/mmbtu and a barrel of oil costs around \$20.00 per barrel. The natural gas feedstock cost is essentially equal to the operating cost and capital cost combined. Figure 17, below, illustrates the potential impact of lowering feedstock costs on the project's internal rate of return.³²

The difference between the product prices and feedstock costs (less capital charges and operating costs) directly affect the project margin. Any reduction in feedstock cost goes directly to the project's bottom line. As Figure 17 illustrates, small changes in the gas price lower the feedstock costs and dramatically improve the project economics.

All else being equal, flared gas is cheaper than pipeline natural gas and Syntroleum plants would use only flared gas. However, other factors that enter into the risk profile of the investment, such as the location of the gas, the size of the gas field, the political environment, and the infrastructure challenges, may counteract flared gas' price advantage. Certainly, lending institutions supporting any Syntroleum project would have key input into these decisions.

Nonetheless, there are other factors besides cost, such as carbon offset projects, that are likely to encourage the use of flared gas. For example, the conversion of flared gas to liquid fuel is an ideal candidate for the World Bank's Prototype Carbon Fund

³² Figure 16 Basis: 25,000 bpd fuels plant, \$23,000 per barrel (42 gallons) of installed capacity capital cost, \$5.00 per bbl operating cost, 10 % discount rate and 15 year life.

("PCF").³³ The World Bank's PCF aims to promote a global market in GHG credits, operating strictly within the framework of the Kyoto Protocol. Memoranda of Understanding have been signed by 12 multinational companies and 5 governments to date, supporting the World Bank's PCF. The World Bank's PCF is projected to have about \$100 million in funding to invest in 12-15 carbon offset projects over the next 3 years.

(ii) Increased Demand for Diesel

Not only is there a need for cleaner diesel fuel to meet Tier 2 standards, but the demand for diesel in the United States transportation sector is growing 3 times faster than gasoline. If this growth in diesel demand continues, 100,000 bpd of incremental diesel fuel will be required each year to keep pace. However, the options for more diesel production capacity are limited. This new supply of diesel fuel will likely come from new refining capacity to produce straight run diesel, from hydrocrackers or fluid catalytic cracking ("FCC") units to produce more diesel pool components and/or existing refinery streams whose current quality limits their use as viable components in the diesel pool. For example, current low-quality refinery streams include cracked gasoils produced from FCC units and delayed cokers. Table 12, below, compares their key properties to straight run diesel and hydrocracked diesel.

Table 13. Typical Refinery Diesel Pool Components

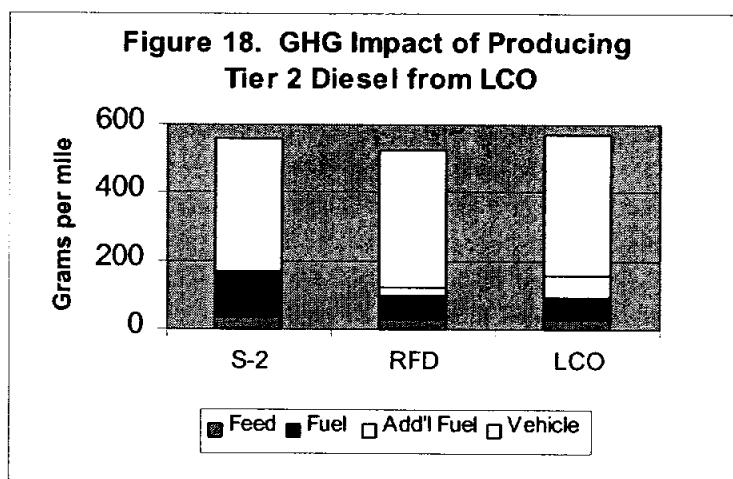

Property	Straight Run Diesel	Hydrocracked Diesel	Coker Diesel	FCC Cycle Oil
API	34	43	29	16
Sulfur, ppm	1K - 5K	10-50	10K – 20 K	1K – 20K
Aromatics, vol%	20	10	45	78
Cetane	51	58	30	20

Some quantities of these cracked gasoils are treated and blended with other straight run diesel streams and hydrocracked diesel streams to produce current EPA diesel fuels. However, the extremely high aromatic and sulfur content of these gasoils prohibit their complete use in the on-road diesel pool. Therefore, in many cases the gasoils end up in the bottom of the refinery product barrel as fuel oil, or in some cases, in off-road diesel. Selling these lower quality product streams is becoming more difficult because the preference for natural gas in many areas of the country, for power generation and industrial use, is eroding their traditional markets. In addition, the use of these lower quality streams may be further limited by the EPA's consideration of imposing lower sulfur levels for off-road diesel.

The net effect of the greater demand for diesel fuel is that refiners will be able to supply the necessary quantities of clean diesel that meets Tier 2 diesel specifications, only if they build new primary crude distillation capacity and/or utilize the resources they have in hand, cracked gasoils. In doing so, this supply of diesel will require more energy for process heat and more natural gas being converted to hydrogen to remove the sulfur (and aromatics). The end result will be higher emission levels of

³³ See <http://www.prototypecarbonfund.org/>

CO₂ and total GHG emissions for each barrel of ultra-low sulfur diesel produced. Figure 18 below shows the potential impact on GHG emissions when a cracked gasoil, such as FCC light cycle oil ("LCO"), is hydrotreated in order to produce clean diesel meeting Tier 2 Sulfur levels. The hydrotreating process parameters are shown in Attachment 3.

When Tier 2 diesel fuel is produced from LCO, the total GHG emissions are 569 g/mi, which is 8% higher than GHG emissions of RFD (525 g/mi). As mentioned above, the total GHG emissions of S-2, produced from natural gas (558 g/mi) only exceed the GHG emissions of RFD by 7%. Thus, total GHG emissions of LCO exceed total GHG emissions of S-2 by approximately 1%. Depending upon the quality of the cracked gasoil streams, the other diesel pool blend components, and various assumptions concerning the hydrotreating process, the GHG emissions could be even higher.

(iii) Displacement of RFG

Although Syntroleum is aware that S-2 is a direct replacement for RFD, not RFG, Syntroleum asserts that S-2 will also displace RFG, albeit somewhat indirectly. As mentioned above, diesel demand in the transportation sector is growing at a rate 3 times faster than gasoline. As shown in Table D, Attachment 4, the growth rate of diesel fuel consumption in the United States from 1992 to 1999 was 4.8%, whereas the growth rate of consumption of gasoline was much lower at 1.6%. This difference is indicative of a trend to replace gasoline engines with cleaner more efficient diesel engines. This trend is reflected in EPA's recent announcement of its Tier 2 standard, which states that automobile manufacturers plan "to increase sales of diesel-powered light-duty trucks and cars over the next few years."³⁴

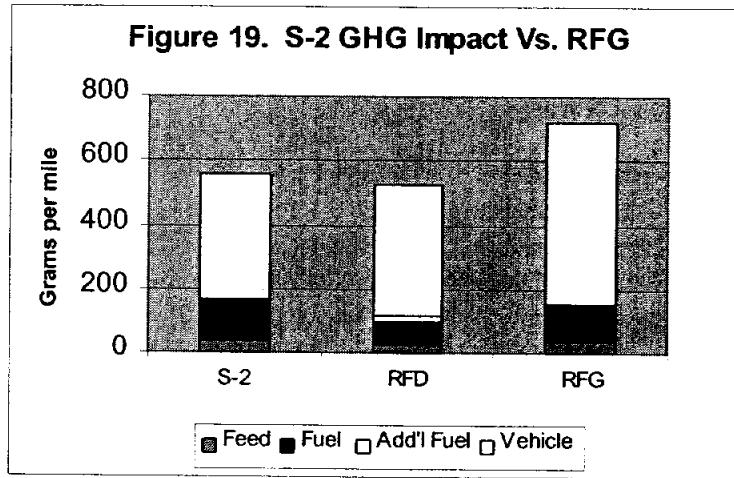

Moreover, according to Ward's Motor Vehicle Facts and Figures 1999, trucks continue to grow in popularity, supplanting cars as the dominant vehicle type in the United States by taking 49% of the new-vehicle market in 1998. In fact, Ward's

³⁴ See <http://www.epa.gov/otaq/diesel.htm>.

commented that: "The biggest factor in the increased truck sales was a 15% rise in deliveries of sport/utility vehicles of 1997, as the segment continued hitting new all-time highs for sales . . . accounting for 17.5% of the combined car and truck market in 1998." Currently, 5% of all these vehicles in the light truck category (0 to 14,000 gross vehicle weight ("GVW")) have diesel engines. The conversion from gasoline to diesel engines is growing each year, as evidenced by 12% growth for the two year period, 1996-1998 and 44% growth for the one year period, 1997-1998. In the heavier portion of this category, where some of the most popular full sized SUVs and larger pickup trucks are found (6,001 to 14,000), the conversion from gasoline engines to diesel engines was even greater, 18% for 1996-1998 and 50% for 1997-1998.

In addition, increased importation of SUVs from foreign automanufacturers that have a strong diesel market in their home countries is likely to increase the number of diesel vehicles in the United States. One year after its introduction to the United States, the sale of the Mercedes M Class SUV increased almost 300%. Heretofore, these manufacturers have largely supplied gasoline engines into the United States because that has been the engine demanded by the United States consumer. With availability of cleaner diesel fuels, manufacturers of diesel powered vehicles should be able to bring their diesel technology and experience into the United States' marketplace.

Figure 19, below, compares the total GHG emissions of S-2 compared to RFD and RFG.

As mentioned above, the GHG emissions of S-2 made from natural gas (558 g/mi) are slightly higher than the GHG emissions of RFD (525 g/mi). However, Figure 19 clearly shows that S-2's GHG emissions are 22% lower than RFG's GHG emissions (720 g/mi). Notably, if 15 to 20% of the S-2 produced displaces RFG, then the overall impact of S-2 on GHG emissions would be neutral.

In light of the first two factors discussed above – flared gas and the increased demand for diesel – S-2's actual GHG emissions during its full fuel-cycle are

substantially equivalent to, or better than, RFD's GHG emissions. Moreover, S-2, even when it is produced from 100% pipeline quality natural gas, has lower GHG emissions than RFG.

C. Other Environmentally Beneficial Attributes of S-2

1. Zero Sulfur in S-2 Enables Use of After Treatment Technologies.

As summarized above, certification of S-2 as an alternative fuel would help reduce direct exhaust emissions of criteria pollutants, N₂O and air toxics. Moreover, certification of S-2 would reduce emissions by enabling the development of new diesel engines and after treatment technologies that have been proven to be highly effective when used with low sulfur fuels,³⁵ and by enabling fuel cell commercialization.

The Tier 2 standards that EPA has announced call for reductions in the sulfur content of gasoline in order to enable advanced catalyst technologies needed to achieve the new emission standards for gasoline engines. In developing the Tier 2 standards, the EPA has adopted a "fuel-neutrality" approach by applying emission standards equally to diesel and gasoline powered vehicles. As a result, the proposed NO_x and PM standards are far more challenging for diesel engine designers. In their Advanced Notice of Proposed Rulemaking ("ANPR"), Control of Diesel Fuel Quality,³⁶ EPA recognized that diesel vehicles may not be able to meet Tier 2 standards without the development of advanced technologies for emissions control. Attachment 5 contains certain excerpts and quotes from the EPA, emphasizing the need for lower sulfur levels in future diesel fuels.

The EPA divides sulfur-sensitive technologies into two categories. One category is for those technologies that are moderately sensitive to sulfur reductions in diesel fuel, and the second is for those technologies that are highly sensitive to sulfur levels in diesel fuel. The potential benefits for several technologies under development today are listed below in Table 13.

Table 14. Sulfur-Sensitive Technologies

	Application	Emission	Potential Reduction %
Category 1– Moderately Sulfur Sensitive			
Exhaust Gas Re-circulation	HD & LD	NO _x	35 - 90
Oxidation Catalysts	HD & LD	PM	20-50
Continuously Regenerating Traps (CRT)	HD & LD	PM	>80
Category 2 – Highly Sulfur Sensitive			
NO _x Storage /Absorption	HD & LD	NO _x	50-90

³⁵ *Navistar's Green Diesel Technology Allows California Air Resources Board to Examine Clean-Diesel Option*, Navistar Int'l Corp., (Jan. 2000), biz.yahoo.com/prnews/00127/ca_navista_1.html.

³⁶ See 64 Fed. Reg. 26142 (May 13, 1999).

Engine manufacturers have suggested that sulfur levels should be capped at 5 to 10 ppm, although the need for even lower levels has also been widely debated. Even for those technologies that require low-sulfur fuel to function, there may be a range of operation in which the technologies may be able to tolerate higher sulfur levels. However, emissions performance of these "sulfur-tolerant" technologies may be further enhanced by additional reductions in the fuel sulfur.

SwRI tested S-2 fuel in a 1999 Volkswagen Golf GL TDI equipped with a turbocharged 1.9 liter CIDI engine equipped with an exhaust gas re-circulation ("EGR") system and an oxidation catalyst exhaust after treatment device. As could be expected given this vehicle's sophisticated anti-pollution devices, the measured results for all emissions were very low, and the differences between the fuels tested much smaller. However, there was one notable exception - the reductions in PM. Figure 20 shows the reductions in PM for the fuels tested versus S-2 for the three EPA test protocols.

During the FTP protocol, which involves city driving, no significant differences were seen among S-2 (which has no sulfur), CARB diesel (which has a low sulfur content), and Swedish City diesel (which contains <1 ppm sulfur). However, for that protocol, the S-2 emissions were 25% lower than the higher sulfur EPA #2 diesel. The lack of difference amongst the fuels in this test was surprising because there was a fairly wide range in sulfur emissions among these fuels in the other tests performed. In the HFET (highway) and US06 (aggressive driving) tests, for example, the differences in sulfur level likely became more pronounced because the catalytic after treatment devices were allowed to warm up and enter into their effective operating ranges. During the HFET test cycle, reductions in PM were seen for all S-2 when compared to the other tested fuels, 71%, 50% and 20% for EPA #2 diesel, CARB diesel and Swedish City diesel, respectively. For the US06 test cycle, 88%, 77%, and 55% reductions in PM were seen compared to EPA #2 diesel, CARB diesel, and Swedish City diesel, respectively.

It is interesting to note that although the Swedish City diesel has a sulfur content of <1 ppm, it generated significantly more PM emissions than S-2. These tests may indicate that the Volkswagen catalytic converter after treatment device was exposed to higher sulfur diesel prior to testing with Swedish City Diesel, and/or sulfur is not the only contributor to PM emissions.

2. The Innovative Design of Syntroleum S-2 Fuel Plants Significantly Reduces the Discharge of Treated Wastewater.

Based on current designs, a commercial scale S-2 plant is expected to use less than half as much makeup water and discharge less than 33% as much treated wastewater as a typical petroleum refinery of similar size. A third party laboratory has recently conducted bench scale tests that show an excellent response from Syntroleum Process water to both steam stripping and aerobic treatment. Further, the biologic treatment tests have shown that Syntroleum Process water is easier to treat than water from a typical refinery or chemical plant. Biologic systems have a more difficult time digesting some of the more complex species in typical refinery water (aromatics, for instance) than those in an S-2 plant water that does not contain those species. This allows facilities to have smaller treatment lagoons or tanks and shorter treatment residence times.

3. S-2 Is More Environmentally Friendly than Conventional Gasoline and Diesel fuel.

The recent problems with methyl-tertiary-butyl ether ("MTBE"), a component of gasoline, contaminating drinking water supplies in California and elsewhere in the United States, highlight the need for environmentally friendly fuels. MTBE is a significant contaminant in water supplies in areas where it is used. Moreover, conventional gasoline and diesel fuel contain sulfur compounds, heavy metals, aromatic hydrocarbons, and other chemical species which may be toxic, carcinogenic, and otherwise harmful to the environment.

In contrast, S-2 fuel consists substantially of saturated paraffins, and is free of the dangerous components present in conventional fuels. In addition, as mentioned above, S-2 fuel produces much lower particulate levels than diesel fuel in current production engines, as demonstrated by recent tests performed by SwRI.

In tests recently performed by Product Safety Labs, in order to compile data for our Material Safety Data Sheets, S-2 was tested for oral toxicity, primary eye irritation and primary skin irritation. As a result of those tests, Syntroleum was found to have no serious health effects. There were no signs of gross toxicity, adverse pharmacologic effect, or abnormal behavior upon ingestion or exposure to the skin. Some slight eye irritation was experienced that cleared up within 48 hours. Based on these tests, S-2 was classified as minimally irritating to the eyes and non-irritating to the skin.

VIII. CONCLUSION

S-2 is an ideal alternative fuel. It is beyond dispute that S-2 meets all three criteria established in Section 301(2) of EPAct, 42 U.S.C.A. § 13211(2) (West 1999). First, S-2 is substantially not petroleum. S-2 is produced solely from natural gas (including flared and vented gas), and therefore, it is 100% non-petroleum.

Second, S-2 has substantial energy security benefits because it is a logical substitute for petroleum-based fuels. There are plentiful natural gas sources in the United States and in foreign countries other than those belonging to OPEC. Accordingly, if S-2 becomes a formidable competitor to petroleum-based diesel, then the United States' reliance on OPEC oil would be reduced.

Finally, S-2's full fuel-cycle emissions of criteria pollutants, N₂O, and air toxics are significantly lower than those of conventional EPA #2 diesel and the ultra low sulfur diesels – CARB diesel and Swedish City diesel. Moreover, the SwRI tests revealed that S-2 has lower GHG emissions during vehicle operation than EPA #2 diesel, CARB diesel, and Swedish City Diesel. Further, S-2 produced from flared gas has significantly lower full fuel-cycle GHG emissions than RFD. In addition, S-2's GHG emissions are dramatically lower (22%) than those of RFG.

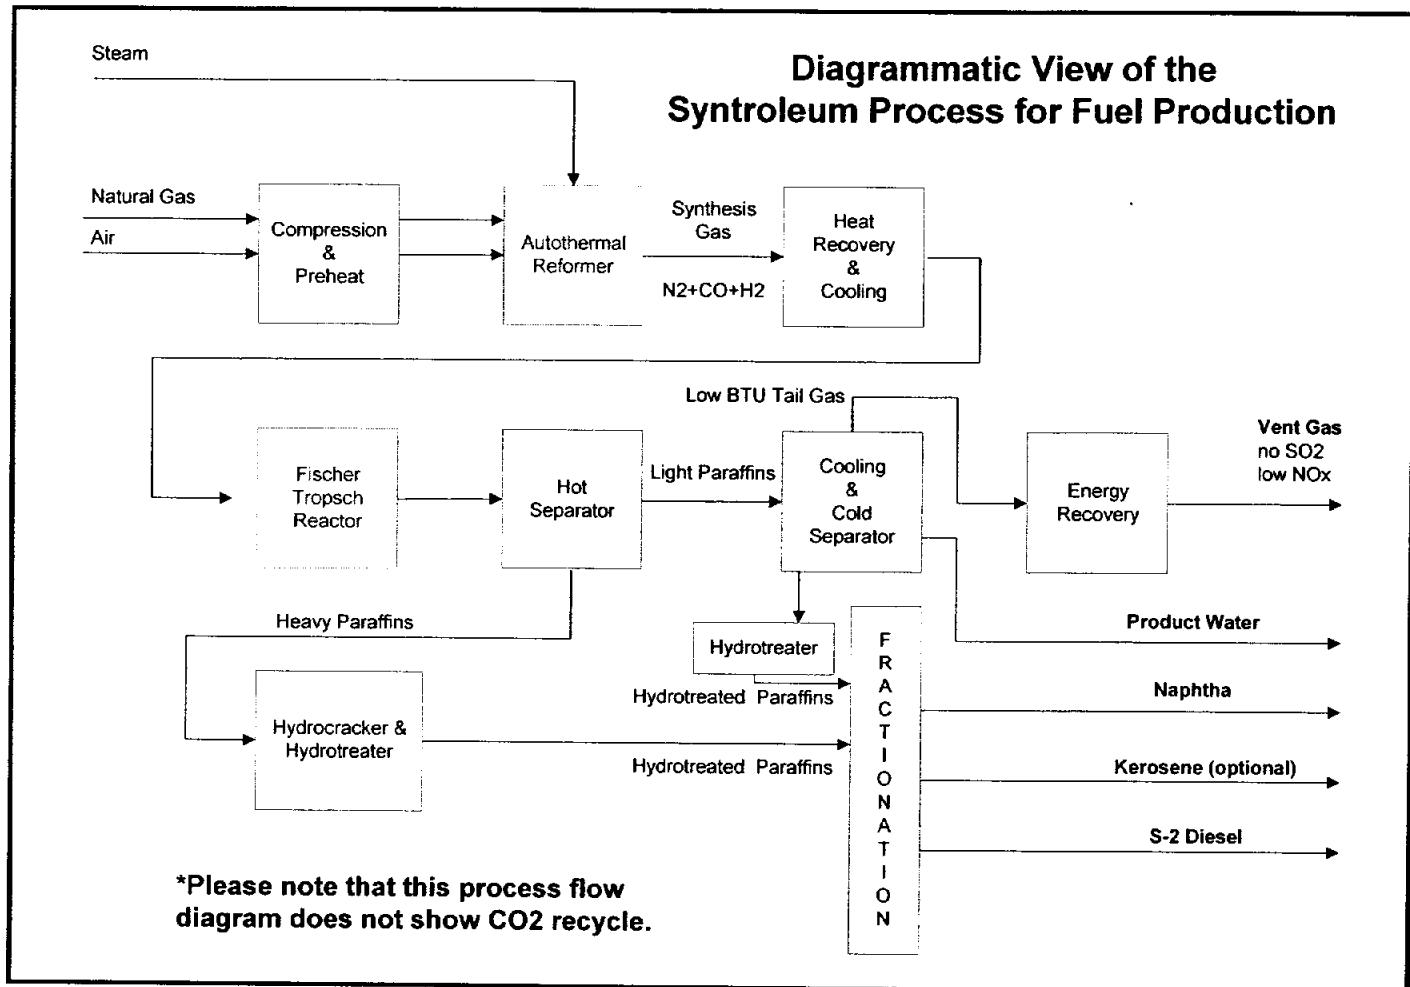

In fact, S-2's only potential drawback is its full fuel-cycle GHG emissions, which were estimated to be approximately 7% higher than those of RFD. However, on its face, this difference is negligible. Moreover, the 7% figure is based upon a preliminary comparison, which does not consider that the S-2 feedstock will be a combination of flared gas and pipeline quality natural gas, or that refining streams for RFD will get dirtier as demand for diesel increases. A more comprehensive comparison shows that S-2's GHG emissions are substantially equivalent to, or indeed lower than, those of RFD. For example, if merely 10% of S-2 is produced from flared gas, then S-2's and RFD's GHG emission levels are identical. And, if S-2's feedstock is more than 10% flared gas, then S-2's GHG emissions are more environmentally beneficial than RFD's. Further, a more comprehensive comparison shows that, given the growing demand for diesel, RFD's GHG emissions are actually 1% higher than those of S-2.

In addition, S-2 is a proven technology neutral fuel that has the potential to revolutionize transportation fuels because it enables dramatic emissions reduction in existing diesel engines, and it could accelerate commercialization of the fuel cell. Designation of S-2 as an alternative fuel would benefit consumers and the fuel industry.

For consumers, S-2 offers the convenience of using existing fuel distribution systems, and it meets vehicle power and range performance expectations. By eliminating the need for specially equipped vehicles or specialized refueling stations, S-2 can break the "chicken and egg" cycle that has challenged the widespread use of other alternative fuels to date. Ultimately, it could enable a seamless transition to future power technologies, such as fuel cells.

For the refining industry, S-2 offers a new path for providing clean transportation fuels. S-2 is a natural compliment to the current product slate of petroleum industry manufacturers. Although S-2 currently is intended to be used as a stand alone, neat fuel, it can also be an effective blending stock for meeting quality specifications for existing fuels during the transitional phases of the new EPA Tier 2 standards.

Figure 1 – Syntroleum Process Flow Chart

Attachment 1 – Summary of SwRI Emission Tests

SwRI tested S-2 fuel against conventional EPA #2 diesel, California CARB specification diesel fuel, and Swedish City diesel fuel to measure criteria pollutants, air toxics, N₂O and GHG emissions. All four fuels were tested in a 5.9-liter Cummins heavy-duty diesel engine on an engine dynamometer, in a Dodge RAM 2500 HD Quad Cab SLT on a chassis dynamometer (heavy light-duty vehicle) and in a 1.9-liter light-duty diesel engine in a 1999 Volkswagen Golf GL TDI on a chassis dynamometer (light-duty vehicle).

For the engine dynamometer test, a single EPA transient test was run. For the chassis dynamometer tests, three EPA test protocols were used: FTP (city), HFET (highway) and US06 (aggressive driving). Summaries of those tests by each test category are shown below. For more detailed information on SwRI tests, please refer to the full tests attached as Appendices A-L, or contact Syntroleum directly.

Attachment 2 - GREET Model

M. Wang and H. S. Hwang of Argonne National Laboratory developed a model to estimate the full fuel-cycle energy and emission impacts of conventional and alternative fuels, including FT diesels, such as S-2, produced from natural gas and flared gas feedstocks. This model is known as the GREET model.³⁷ The full fuel-cycle incorporates the following three stages to evaluate energy use and emissions: (1) feedstock production, including transportation to fuel production facilities, (2) fuel production, including transportation and distribution to fueling locations, and (3) vehicle operation.

Syntroleum utilized the GREET model to compare full fuel-cycle energy use and emissions of synthetic paraffin diesel (similar to S-2) produced from both natural gas and flared gas to the full fuel-cycle energy requirements to produce RFG and RFD. Additionally, Syntroleum used the GREET model in conjunction with calculations external to the GREET model (see Attachment 3) to determine the effects on GHG emissions when producing RFD from other refinery process streams, such as LCO. To make the desired comparisons, Syntroleum modified minor input to the GREET model, as provided for in the model design. Modifications to the GREET model for these calculations are listed in Section 1, which shows both the input change locations and variables modified for each feedstock modeled. Section 2 presents in tabular form the energy and emission results of the GREET for the reference fuels and S-2. Please note that the energy results are expressed in Btu per mile and the emission results are expressed in grams per mile.

Section 1. Modifications and Input into the GREET model

General Model Options

Attachment 3 – Syntroleum Calculations

The demand for diesel fuel in the United States (as well as worldwide demand) is expected to grow at a rate faster than the demand for transportation fuels in general. Thus, refiners will be challenged to meet the growing demand for diesel fuel, while at the same time producing the high quality diesel fuel that is now likely to be established at 15 ppm. While it is possible to purchase diesel blend stocks from other refiners, the supply of these “surplus clean” distillate streams is limited. Alternatively, additional crude processing capacity or reconfiguration of upgrading equipment or cutpoint control could create increased supply of clean blend components to the diesel pool. However, the most likely scenario is the installation of additional processing units to upgrade existing, lower quality (high sulfur and aromatic content) distillate streams within the refinery. These dirtier distillate streams include LCO and coker gasoils, which are commonly sold as heating oil, residual fuel oil, and off-road diesel for which there are less environmental restrictions.

Hydrogen will be the key element for meeting the future diesel specifications. More hydrogen will be required to upgrade the existing pool of diesel (currently estimated to be 350 ppm) to meet the anticipated 15 ppm Tier 2 standard.³⁸ Even more will be required to upgrade the less-desirable gasoils into more desirable and needed diesel fuels. This situation is further exacerbated by gasoline regulations that limit the aromatic content of reformulated gasoline, which will require reduction of naphtha reforming severity, and thereby a reduction of byproduct hydrogen. This byproduct hydrogen could have been used for desulfurization of the dirty distillate streams. Refiners will need to produce and/or purchase more hydrogen for desulfurization (and de facto aromatization) if lower quality distillate streams are used as feedstock for the production of 15-ppm sulfur on-road diesel.

The GREET model used in our analysis of full fuel-cycle energy and emissions of S-2 includes reformulated gasoline and diesel fuels as long term scenarios. Baseline sulfur levels for these scenarios are 30 ppm for the RFG and 50 ppm for the diesel. In order to calculate the additional energy and emissions that would accompany a reduction of sulfur to the anticipated Tier 2 diesel sulfur level of 15 ppm, Syntroleum estimated the hydrogen and energy demands of a typical stand alone hydrotreater to reduce on-road diesel pool sulfur from 50 ppm to 15 ppm. The energy requirements and emissions of hydrotreating LCO to meet the Tier 2 sulfur specifications are also evaluated.

Although each individual refiner will produce clean diesel based on its own individual resources, Syntroleum believes that to reduce the current diesel pool from approximately 350 ppm to 15 ppm, or to process the additional LCO, additional refining and hydrotreating resources will be required. Section 1 below lists the feed, fuel and operating parameters for hydrotreating and hydrogen production to produce 15 ppm sulfur diesel from selected refinery streams. Section 2 lists the process requirements and the energy requirements and emissions for each diesel stream.

³⁸ See *supra*, note 26.

Section 3 identifies the references used to develop these parameters and calculations. As mentioned elsewhere, the resulting energy and emissions required to treat these diesel fuels was added to the results of the GREET model shown in Attachment 2.

Section 1. Operating Parameters

A. Hydrotreater

1. Stand alone unit, energy and emissions added to GREET results
2. Purchased pipeline hydrogen
3. Operating severity as required to produce 15 ppm diesel product
4. Aromatics reduction 40 to 70 %, feedstock dependent (see below)
5. Chemical hydrogen consumption, feedstock dependent (see below)
6. Bleed hydrogen and solution loss make-up, 1 # per bbl.
7. Process heat including sulfur recovery, feedstock dependent (see below)
8. Total volumetric gains, 3 to 4%
9. Volumetric loss in diesel boiling range product, 2%
10. Process fuel 50% natural gas; 50% fuel oil
11. Emission factors for hydrotreater based on combustion of process fuel
12. Process fuel combustion emissions based on GREET model

B. Hydrogen Unit

1. Offsite Steam Methane Reformer using natural gas as feed and fuel
2. Natural gas feed quantities (per mmBtu Hydrogen requirement) based on GREET model
3. Process fuel and steam credits based on GREET model
4. Emission factors for SMR based on GREET model

Source: *Alternatives to Traditional Transportation Fuels, 1999 – Table 10*, DOE/EIA, (Jan. 2000), http://www.eia.doe.gov/cneaf/solar.renewables/alt_trans_fuel98/atf_99.html

\a\ The remaining portion of 85% methanol and both ethanol fuels is gasoline.

Consumption data include the gasoline portion of the fuel.

\b\ 1995 and 1996 estimates have been revised.

\c\ Includes a very small amount of other ethers, primarily Tertiary Amyl Methyl Ether (TAME) and Ethyl Tertiary Butyl Ether (ETBE).

\d\ Gasoline consumption includes ethanol in gasohol and MTBE.

\e\ Total fuel consumption is the sum of alternative fuel, gasoline, and diesel consumption. Oxygenate consumption is included in gasoline consumption.

Notes: Fuel quantities are expressed in a common base unit of gasoline-equivalent gallons to allow comparisons of different fuel types. Gasoline-equivalent gallons do not represent gasoline displacement. Gasoline equivalent is computed by dividing the lower heating value of the alternative fuel by the lower heating value of gasoline and multiplying this result by the alternative fuel consumption value. Lower heating value refers to the Btu content per unit of fuel excluding the heat produced by condensation of water vapor in the fuel. Totals may not equal sum of components due to independent rounding. Estimates for 1997 are revised. Estimates for 1998 are preliminary. Estimates for 1999 (in italics) are based on plans or projections. Estimates for historical years may be revised in future reports if new information becomes available.

Attachment 5 – EPA Comments on Diesel Fuel Quality

Prior to making the May 17, 2000 announcement regarding Tier 2 standards for diesel fuel, EPA made the following statements concerning diesel fuel quality in its ANPR:³⁹

"These advanced sulfur-sensitive technologies have the potential to reduce diesel engine NO_x emissions by up to 75 percent and PM emissions by 80 percent or more...these promising new technologies may allow a step change in the diesel emissions control of a magnitude comparable to that ushered in by the automotive catalytic converter in the 1970's. However, it appears that changes in diesel fuel quality may be needed to bring this step change about."

"These studies have also determined that engine design and fuel properties are interdependent in their effects on emissions. Combinations of particulate traps, lean NO_x catalysts and fuel reformulation could reduce emissions of particulates by 80 to 95 percent and NO_x by 60 to 90 percent according to a recent assessment."⁴⁰

Although the EPA recognized some benefit to lowering emissions with changes in fuel density, aromatic content and cetane number in its ANPR, it identified sulfur reduction in diesel fuel as being the most important:

"Reducing the sulfur content of diesel fuel has the potential to provide large indirect technology-enabling benefits in addition to some amount of direct emission benefits. In fact, sulfur reduction appears to be the only fuel change with potential to enable new technologies needed to meet Tier 2 light-duty or anticipated future heavy-duty standards."

Additionally, the EPA saw a secondary effect on lowering the sulfur level in fuels:

"Although the impetus for near-term action on diesel fuel quality comes from our efforts set fuel-neutral Tier 2 standards for the light-duty diesel market, any emissions control technologies that prove effective in light-duty diesel applications are likely to be effective with heavy-duty highway engines as well. Thus higher quality diesel fuel for heavy-duty applications, combined with more stringent heavy-duty emission standards that effectively introduce the new technologies, could provide large environmental benefits, though perhaps on a different implementation schedule than that required for the light-duty program. This might take the form of a phased in program, involving a regulated grade of premium fuel that is initially focused on servicing the light-duty diesel fleet, but that gradually widens its market penetration to fulfill the expanding need created by sales of new heavy-duty vehicles that also employ the advanced technologies . . . In addition to enabling new control technologies, the use of higher quality diesel fuel is likely to improve the emissions

performance of the existing fleet of diesel engines as well Eventually these advanced technologies could also find applications in nonroad equipment"

SUMMED SPECIATED VALUES	79	85	81.7	84	86	85.0

A - 2,2-Dimethylpentane and methylcyclopentane co-elute. GC peak area split equally between the two compounds.

B - 3-Methyl-3-ethy-pentane co-elutes with reported compound. Not reported separately.

C - Cis-1,4-Dimethylcyclohexane co-elutes with reported compound. Not reported separately.

D - Propylcyclopentane co-elutes with reported compound. Not reported separately.

E - 2,5-Dimethylheptane and 3,5-dimethylheptane co-elute. GC peak area split equally between the two compounds.

F - Decane and isobutylbenzene co-elute. GC peak area split equally between the two compounds.

G - n-Butylbenzene co-elutes with reported compound. Not reported separately.

H - Isobutyraldehyde and methyl ethyl ketone co-elute. LC peak area split equally between the two compounds.

A - 2,2-Dimethylpentane and methylcyclopentane co-elute. GC peak area split equally between the two compounds.

B - 3-Methyl-3-ethy-pentane co-elutes with reported compound. Not reported separately.

C - Cis-1,4-Dimethylcyclohexane co-elutes with reported compound. Not reported separately.

D - Propylcyclopentane co-elutes with reported compound. Not reported separately.

E - 2,5-Dimethylheptane and 3,5-dimethylheptane co-elute. GC peak area split equally between the two compounds.

F - Decane and isobutylbenzene co-elute. GC peak area split equally between the two compounds.

G - n-Butylbenzene co-elutes with reported compound. Not reported separately.

H - Isobutyraldehyde and methyl ethyl ketone co-elute. LC peak area split equally between the two compounds.

A - 2,2-Dimethylpentane and methylcyclopentane co-elute. GC peak area split equally between the two compounds.

B - 3-Methyl-3-ethy-pentane co-elutes with reported compound. Not reported separately.

C - Cis-1,4-Dimethylcyclohexane co-elutes with reported compound. Not reported separately.

D - Propylcyclopentane co-elutes with reported compound. Not reported separately.

E - 2,5-Dimethylheptane and 3,5-dimethylheptane co-elute. GC peak area split equally between the two compounds.

F - Decane and isobutylbenzene co-elute. GC peak area split equally between the two compounds.

G - n-Butylbenzene co-elutes with reported compound. Not reported separately.

H - Isobutyraldehyde and methyl ethyl ketone co-elute. LC peak area split equally between the two compounds.

SUMMED SPECIATED VALUES	34	43	38.5	22	27	24.6

A - 2,2-Dimethylpentane and methylcyclopentane co-elute. GC peak area split equally between the two compounds.

B - 3-Methyl-3-ethy-pentane co-elutes with reported compound. Not reported separately.

C - Cis-1,4-Dimethylcyclohexane co-elutes with reported compound. Not reported separately.

D - Propylcyclopentane co-elutes with reported compound.. Not reported separately.

E - 2,5-Dimethylheptane and 3,5-dimethylheptane co-elute. GC peak area split equally between the two compounds.

F - Decane and isobutylbenzene co-elute. GC peak area split equally between the two compounds.

G - n-Butylbenzene co-elutes with reported compound. Not reported separately.

H - Isobutyraldehyde and methyl ethyl ketone co-elute. LC peak area split equally between the two compounds.

SUMMED SPECIATED VALUES	10	14	11.8	12	9	10.4

A - 2,2-Dimethylpentane and methylcyclopentane co-elute. GC peak area split equally between the two compounds.

B - 3-Methyl-3-ethy-pentane co-elutes with reported compound. Not reported separately.

C - Cis-1,4-Dimethylcyclohexane co-elutes with reported compound. Not reported separately.

D - Propylcyclopentane co-elutes with reported compound. Not reported separately.

E - 2,5-Dimethylheptane and 3,5-dimethylheptane co-elute. GC peak area split equally between the two compounds.

F - Decane and isobutylbenzene co-elute. GC peak area split equally between the two compounds.

G - n-Butylbenzene co-elutes with reported compound. Not reported separately.

H - Isobutyraldehyde and methyl ethyl ketone co-elute. LC peak area split equally between the two compounds.

SUMMED SPECIATED VALUES	9	11	9.7	12	8	10.1

A - 2,2-Dimethylpentane and methylcyclopentane co-elute. GC peak area split equally between the two compounds.

B - 3-Methyl-3-ethy-pentane co-elutes with reported compound. Not reported separately.

C - Cis-1,4-Dimethylcyclohexane co-elutes with reported compound. Not reported separately.

D - Propylcyclopentane co-elutes with reported compound. Not reported separately.

E - 2,5-Dimethylheptane and 3,5-dimethylheptane co-elute. GC peak area split equally between the two compounds.

F - Decane and isobutylbenzene co-elute. GC peak area split equally between the two compounds.

G - n-Butylbenzene co-elutes with reported compound. Not reported separately.

H - Isobutyraldehyde and methyl ethyl ketone co-elute. LC peak area split equally between the two compounds.

SUMMED SPECIATED VALUES	95	87	91.3	103	92	97.2

A - 2,2-Dimethylpentane and methylcyclopentane co-elute. GC peak area split equally between the two compounds.

B - 3-Methyl-3-ethy-pentane co-elutes with reported compound. Not reported separately.

C - Cis-1,4-Dimethylcyclohexane co-elutes with reported compound. Not reported separately.

D - Propylcyclopentane co-elutes with reported compound. Not reported separately.

E - 2,5-Dimethylheptane and 3,5-dimethylheptane co-elute. GC peak area split equally between the two compounds.

F - Decane and isobutylbenzene co-elute. GC peak area split equally between the two compounds.

G - n-Butylbenzene co-elutes with reported compound. Not reported separately.

H - Isobutyraldehyde and methyl ethyl ketone co-elute. LC peak area split equally between the two compounds.

SUMMED SPECIATED VALUES	52	39	45.4	46	50	47.9

A - 2,2-Dimethylpentane and methylicyclopentane co-elute. GC peak area split equally between the two compounds.

B - 3-Methyl-3-ethy-pentane co-elutes with reported compound. Not reported separately.

C - Cis-1,4-Dimethylcyclohexane co-elutes with reported compound. Not reported separately.

D - Propylcyclopentane co-elutes with reported compound. Not reported separately.

E - 2,5-Dimethylheptane and 3,5-dimethylheptane co-elute. GC peak area split equally between the two compounds.

F - Decane and isobutylbenzene co-elute. GC peak area split equally between the two compounds.

G - n-Butylbenzene co-elutes with reported compound. Not reported separately.

H - Isobutyraldehyde and methyl ethyl ketone co-elute. LC peak area split equally between the two compounds.

A - 2,2-Dimethylpentane and methylcyclopentane co-elute. GC peak area split equally between the two compounds.

B - 3-Methyl-3-ethy-pentane co-elutes with reported compound. Not reported separately.

C - Cis-1,4-Dimethylcyclohexane co-elutes with reported compound. Not reported separately.

D - Propylcyclopentane co-elutes with reported compound. Not reported separately.

E - 2,5-Dimethylheptane and 3,5-dimethylheptane co-elute. GC peak area split equally between the two compounds.

F - Decane and isobutylbenzene co-elute. GC peak area split equally between the two compounds.

G - n-Butylbenzene co-elutes with reported compound. Not reported separately.

H - Isobutyraldehyde and methyl ethyl ketone co-elute. LC peak area split equally between the two compounds.

SUMMED SPECIATED VALUES	36	31	33.6	27	19	22.8

A - 2,2-Dimethylpentane and methylcyclopentane co-elute. GC peak area split equally between the two compounds.

B - 3-Methyl-3-ethyl-pentane co-elutes with reported compound. Not reported separately.

C - Cis-1,4-Dimethylcyclohexane co-elutes with reported compound. Not reported separately.

D - Propylcyclopentane co-elutes with reported compound. Not reported separately.

E - 2,5-Dimethylheptane and 3,5-dimethylheptane co-elute. GC peak area split equally between the two compounds.

F - Decane and isobutylbenzene co-elute. GC peak area split equally between the two compounds.

G - n-Butylbenzene co-elutes with reported compound. Not reported separately.

H - Isobutyraldehyde and methyl ethyl ketone co-elute. LC peak area split equally between the two compounds.

SUMMED SPECIATED VALUES	11	14	12.6	6	7	6.6

A - 2,2-Dimethylpentane and methylcyclopentane co-elute. GC peak area split equally between the two compounds.

B - 3-Methyl-3-ethy-pentane co-elutes with reported compound. Not reported separately.

C - Cis-1,4-Dimethylcyclohexane co-elutes with reported compound. Not reported separately.

D - Propylcyclopentane co-elutes with reported compound. Not reported separately.

E - 2,5-Dimethylheptane and 3,5-dimethylheptane co-elute. GC peak area split equally between the two compounds.

F - Decane and isobutylbenzene co-elute. GC peak area split equally between the two compounds.

G - n-Butylbenzene co-elutes with reported compound. Not reported separately.

H - Isobutyraldehyde and methyl ethyl ketone co-elute. LC peak area split equally between the two compounds.

A - 2,2-Dimethylpentane and methylcyclopentane co-elute. GC peak area split equally between the two compounds.

B - 3-Methyl-3-ethy-pentane co-elutes with reported compound. Not reported separately.

C - Cis-1,4-Dimethylcyclohexane co-elutes with reported compound. Not reported separately.

D - Propylcyclopentane co-elutes with reported compound. Not reported separately.

E - 2,5-Dimethylheptane and 3,5-dimethylheptane co-elute. GC peak area split equally between the two compounds.

F - Decane and isobutylbenzene co-elute. GC peak area split equally between the two compounds.

G - n-Butylbenzene co-elutes with reported compound. Not reported separately.

H - Isobutyraldehyde and methyl ethyl ketone co-elute. LC peak area split equally between the two compounds.

A - 2,2-Dimethylpentane and methylcyclopentane co-elute. GC peak area split equally between the two compounds.

B - 3-Methyl-3-ethy-pentane co-elutes with reported compound. Not reported separately.

C - Cis-1,4-Dimethylcyclohexane co-elutes with reported compound. Not reported separately.

D - Propylcyclopentane co-elutes with reported compound. Not reported separately.

E - 2,5-Dimethylheptane and 3,5-dimethylheptane co-elute. GC peak area split equally between the two compounds.

F - Decane and isobutylbenzene co-elute. GC peak area split equally between the two compounds.

G - n-Butylbenzene co-elutes with reported compound. Not reported separately.

H - Isobutyraldehyde and methyl ethyl ketone co-elute. LC peak area split equally between the two compounds.

SUMMED SPECIATED VALUES	77	70	73.4	70	64	67.0

A - 2,2-Dimethylpentane and methylcyclopentane co-elute. GC peak area split equally between the two compounds.

B - 3-Methyl-3-ethy-pentane co-elutes with reported compound. Not reported separately.

C - Cis-1,4-Dimethylcyclohexane co-elutes with reported compound. Not reported separately.

D - Propylcyclopentane co-elutes with reported compound. Not reported separately.

E - 2,5-Dimethylheptane and 3,5-dimethylheptane co-elute. GC peak area split equally between the two compounds.

F - Decane and isobutylbenzene co-elute. GC peak area split equally between the two compounds.

G - n-Butylbenzene co-elutes with reported compound. Not reported separately.

H - Isobutyraldehyde and methyl ethyl ketone co-elute. LC peak area split equally between the two compounds.

A - 2,2-Dimethylpentane and methylcyclopentane co-elute. GC peak area split equally between the two compounds.

B - 3-Methyl-3-ethy-pentane co-elutes with reported compound. Not reported separately.

C - Cis-1,4-Dimethylcyclohexane co-elutes with reported compound. Not reported separately.

D - Propylcyclopentane co-elutes with reported compound. Not reported separately.

E - 2,5-Dimethylheptane and 3,5-dimethylheptane co-elute. GC peak area split equally between the two compounds.

F - Decane and isobutylbenzene co-elute. GC peak area split equally between the two compounds.

G - n-Butylbenzene co-elutes with reported compound. Not reported separately.

H - Isobutyraldehyde and methyl ethyl ketone co-elute. LC peak area split equally between the two compounds.

A - 2,2-Dimethylpentane and methylcyclopentane co-elute. GC peak area split equally between the two compounds.

B - 3-Methyl-3-ethyl-pentane co-elutes with reported compound. Not reported separately.

C - Cis-1,4-Dimethylcyclohexane co-elutes with reported compound. Not reported separately.

D - Propylcyclopentane co-elutes with reported compound. Not reported separately.

E - 2,5-Dimethylheptane and 3,5-dimethylheptane co-elute. GC peak area split equally between the two compounds.

F - Decane and isobutylbenzene co-elute. GC peak area split equally between the two compounds.

G - n-Butylbenzene co-elutes with reported compound. Not reported separately.

H - Isobutyraldehyde and methyl ethyl ketone co-elute. LC peak area split equally between the two compounds.

A - 2,2-Dimethylpentane and methylcyclopentane co-elute. GC peak area split equally between the two compounds.

B - 3-Methyl-3-ethy-pentane co-elutes with reported compound. Not reported separately.

C - Cis-1,4-Dimethylcyclohexane co-elutes with reported compound. Not reported separately.

D - Propylcyclopentane co-elutes with reported compound. Not reported separately.

E - 2,5-Dimethylheptane and 3,5-dimethylheptane co-elute. GC peak area split equally between the two compounds.

F - Decane and isobutylbenzene co-elute. GC peak area split equally between the two compounds.

G - n-Butylbenzene co-elutes with reported compound. Not reported separately.

H - Isobutyraldehyde and methyl ethyl ketone co-elute. LC peak area split equally between the two compounds.

SUMMED SPECIATED VALUES	51	59	54.7	79	75	77.1

A - 2,2-Dimethylpentane and methylcyclopentane co-elute. GC peak area split equally between the two compounds.

B - 3-Methyl-3-ethy-pentane co-elutes with reported compound. Not reported separately.

C - Cis-1,4-Dimethylcyclohexane co-elutes with reported compound. Not reported separately.

D - Propylcyclopentane co-elutes with reported compound. Not reported separately.

E - 2,5-Dimethylheptane and 3,5-dimethylheptane co-elute. GC peak area split equally between the two compounds.

F - Decane and isobutylbenzene co-elute. GC peak area split equally between the two compounds.

G - n-Butylbenzenes co-elutes with reported compound. Not reported separately.

H - Isobutyraldehyde and methyl ethyl ketone co-elute. LC peak area split equally between the two compounds.
